| Professor-style explanation | <p>The slide 'Projection Specification' explains how camera geometry turns a 3D scene into image coordinates. In view space, objects are described relative to the camera. The projection matrix then maps that camera-centered geometry into clip space, where the viewing volume and clipping boundaries can be handled consistently. Perspective projection uses the homogeneous coordinate so that the later divide by <math>w</math> creates foreshortening: farther objects occupy less image space. Orthographic projection removes that depth-based size change and keeps parallel structures visually parallel. The terms describe camera-to-screen mapping: - Specified by Height Angle, Aspect Ratio, / Near Plane Distance and Far Plane Distance / - Examples of Aspect Ratio / - NTSC 4 : 3, HDTV 16 : 9 / - Cinema 2.35 : 1, 2.39 : 1, 2.40 : 1, or 2.55 : 1. View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport. The object chain is view-space position, projection matrix, clip coordinate, normalized device coordinate, and viewport coordinate. The slide is therefore connecting camera setup, visual appearance, and the numeric coordinate pipeline that rasterization later consumes.</p> |
| Technical commentary        | <p>This slide is about Projection Specification. The projection objects on the slide convert view-space geometry into clip coordinates, normalized coordinates, and finally screen-related positions. The terms describe camera-to-screen mapping: - Specified by Height Angle, Aspect Ratio, / Near Plane Distance and Far Plane Distance / - Examples of Aspect Ratio / - NTSC 4 : 3, HDTV 16 : 9 / - Cinema 2.35 : 1, 2.39 : 1, 2.40 : 1, or 2.55 : 1. View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Projection controls both image composition and depth precision, so it affects visibility and rasterization later.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | <p>Can you explain how 'Projection Specification' changes positions before rasterization?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Page 36                     | View Angle                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | <p>The slide 'View Angle' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Parallel projection: no viewing angle as rays are parallel / - Perspective projection: / viewing angle determines perspective distortion in the image / - Specification / - Through the viewing angle in height (field of view in y, fovy). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p>                     |
| Technical commentary        | <p>This slide is about View Angle. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Parallel projection: no viewing angle as rays are parallel / - Perspective projection: / viewing angle determines perspective distortion in the image / - Specification / - Through the viewing angle in height (field of view in y, fovy). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | <p>The slide 'Clipping Planes' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Position of the planes is determined by the distance along the look vector: / near distance and far distance / - Near plane hides objects that are behind or too close to the camera / - Far plane hides objects that are too far away (and may be hard to spot) / <math>\Rightarrow</math> Reduction of rendering overhead. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.</p> |

| Technical commentary | This slide is about Clipping Planes. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Position of the planes is determined by the distance along the look vector: / near distance and far distance / - Near plane hides objects that are behind or too close to the camera / - Far plane hides objects that are too far away (and may be hard to spot) / $\Rightarrow$ Reduction of rendering overhead. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. |
| Why it matters       | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself       | Can you decide what is accepted, rejected, or newly intersected in 'Clipping Planes'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Source cue                  | Functions to describe the view volume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Professor-style explanation | The slide '4.4 Specifying Projections in OpenGL' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: Functions to describe the view volume. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about 4.4 Specifying Projections in OpenGL. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: Functions to describe the view volume. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in '4.4 Specifying Projections in OpenGL'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Page 39                     | Projection Matrix Generation 1/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | The slide 'Projection Matrix Generation 1/3' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Convenient generation of perspective projection matrix with GLM / - glm::perspective(fovy, aspect, near, far) / $h \cdot n \cdot f / \text{aspect}$ / fovy fovy. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Projection Matrix Generation 1/3. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Convenient generation of perspective projection matrix with GLM / - glm::perspective(fovy, aspect, near, far) / $h \cdot n \cdot f / \text{aspect}$ / fovy fovy. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you state the coordinate space before and after 'Projection Matrix Generation 1/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Page 40                     | Projection Matrix Generation 2/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Source cue                  | - Alternative generation of perspective projection matrix with GLM / - glm::frustum(left, right, bottom, top, near, far) / (r, t, -n) / $z = -f$ (far plane) / (l, b, -n)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Professor-style explanation | The slide 'Projection Matrix Generation 2/3' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Alternative generation of perspective projection matrix with GLM / - glm::frustum(left, right, bottom, top, near, far) / (r, t, -n) / $z = -f$ (far plane) / (l, b, -n). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Projection Matrix Generation 2/3. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Alternative generation of perspective projection matrix with GLM / - glm::frustum(left, right, bottom, top, near, far) / (r, t, -n) / z = -f (far plane) / (l, b, -n). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. |
| Why it matters       | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself       | Can you state the coordinate space before and after 'Projection Matrix Generation 2/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | The slide 'Projection Matrix Generation 3/3' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Implementation of glm::perspective / detail::tmat4x4<T> perspective(T const & fovy, T const & aspect, / T const & near, T const & far) { / T const & l, r, b, t; / t = n * tan(fovy * M_PI / 360.0). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Projection Matrix Generation 3/3. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Implementation of glm::perspective / detail::tmat4x4<T> perspective(T const & fovy, T const & aspect, / T const & near, T const & far) { / T const & l, r, b, t; / t = n * tan(fovy * M_PI / 360.0). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you state the coordinate space before and after 'Projection Matrix Generation 3/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Page 42                     | Orthographic Matrix Specification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide 'Orthographic Matrix Specification' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Convenient generation of parallel projection matrix with GLM / - glm::ortho(left, right, bottom, top, near, far) / (r, t, -f) / z = -f (far plane) / z = -n (near plane). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Orthographic Matrix Specification. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Convenient generation of parallel projection matrix with GLM / - glm::ortho(left, right, bottom, top, near, far) / (r, t, -f) / z = -f (far plane) / z = -n (near plane). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you state the coordinate space before and after 'Orthographic Matrix Specification'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Source cue                  | Step-wise transformation of a cuboid into a cube                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide '4.5 Orthographic Projection Derivation' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: Step-wise transformation of a cuboid into a cube. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear.                                                                                                                      |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Technical commentary | This slide is about 4.5 Orthographic Projection Derivation. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: Step-wise transformation of a cuboid into a cube. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. |
| Why it matters       | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself       | Can you state the coordinate space before and after '4.5 Orthographic Projection Derivation'?                                                                                                                                                                                                                                                                                                                                                        |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Page 44                     | Canonical View Volume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source cue                  | - Canonical view volume - simplest possible view volume / - Cube centered at the origin / - Cube faces $x = \pm 1$ , $y = \pm 1$ , $z = \pm 1$ / - Defined in a left-handed coordinate system (LHS) / (1, 1, 1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Professor-style explanation | The slide 'Canonical View Volume' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Canonical view volume - simplest possible view volume / - Cube centered at the origin / - Cube faces $x = \pm 1$ , $y = \pm 1$ , $z = \pm 1$ / - Defined in a left-handed coordinate system (LHS) / (1, 1, 1). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Canonical View Volume. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Canonical view volume - simplest possible view volume / - Cube centered at the origin / - Cube faces $x = \pm 1$ , $y = \pm 1$ , $z = \pm 1$ / - Defined in a left-handed coordinate system (LHS) / (1, 1, 1). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself              | Can you state the coordinate space before and after 'Canonical View Volume'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|            |                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Orthographic Projection 1/4' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Transform right-handed view volume specified as $[l, r] \times [b, t] \times [-n, -f]$ / into left-handed canonical view volume $[-1, 1] \times [-1, 1] \times [-1, 1]$ / and then create the projected image by neglecting z-values / $(r, t, -f)$ / $(1, 1, 1)$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Orthographic Projection 1/4. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Transform right-handed view volume specified as $[l, r] \times [b, t] \times [-n, -f]$ / into left-handed canonical view volume $[-1, 1] \times [-1, 1] \times [-1, 1]$ / and then create the projected image by neglecting z-values / $(r, t, -f)$ / $(1, 1, 1)$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you state the coordinate space before and after 'Orthographic Projection 1/4'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Page 46                     | Orthographic Projection 2/4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Source cue                  | - Let $p(x, y, z)$ be a model point and $q(x', y', z')$ its transformed point / - The desired pixel $(x, y)$ results from orthographic projection of $q$ / $p$ / onto the plane $z = -1$ : $x = x'$ and $y = y' / p$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | <p>The slide 'Orthographic Projection 2/4' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Let <math>p(x, y, z)</math> be a model point and <math>q(x', y', z')</math> its transformed point / - The desired pixel <math>(x, y)</math> results from orthographic projection of <math>q / p</math> onto the plane <math>z = -1</math>: <math>x = x'</math> and <math>y = y' / p</math>. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear.</p> |
| Technical commentary        | <p>This slide is about Orthographic Projection 2/4. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Let <math>p(x, y, z)</math> be a model point and <math>q(x', y', z')</math> its transformed point / - The desired pixel <math>(x, y)</math> results from orthographic projection of <math>q / p</math> onto the plane <math>z = -1</math>: <math>x = x'</math> and <math>y = y' / p</math>. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | <p>A wrong coordinate-space assumption can make correct formulas produce wrong images.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | <p>Can you state the coordinate space before and after 'Orthographic Projection 2/4'?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | <p>The slide 'Orthographic Projection 3/4' explains how camera geometry turns a 3D scene into image coordinates. In view space, objects are described relative to the camera. The projection matrix then maps that camera-centered geometry into clip space, where the viewing volume and clipping boundaries can be handled consistently. Perspective projection uses the homogeneous coordinate so that the later divide by <math>w</math> creates foreshortening: farther objects occupy less image space. Orthographic projection removes that depth-based size change and keeps parallel structures visually parallel. The terms describe camera-to-screen mapping: - Step 2, scale cuboid from step 1 into cube / - Original cuboid bounds are <math>/ r - l \ r - l \ t - b \ t - b \ f - n \ f - n / - , x - , x - , / 2 \ 2 \ 2 \ 2 \ 2 \ 2</math>. View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport. The object chain is view-space position, projection matrix, clip coordinate, normalized device coordinate, and viewport coordinate. The slide is therefore connecting camera setup, visual appearance, and the numeric coordinate pipeline that rasterization later consumes.</p> |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Technical commentary | This slide is about Orthographic Projection 3/4. The projection objects on the slide convert view-space geometry into clip coordinates, normalized coordinates, and finally screen-related positions. The terms describe camera-to-screen mapping: - Step 2, scale cuboid from step 1 into cube / - Original cuboid bounds are $r - l, r - l, t - b, t - b, f - n, f - n$ , $x - , x - , / 2$<br>$2 \ 2 \ 2 \ 2 \ 2$ . View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport. |
| Why it matters       | Projection controls both image composition and depth precision, so it affects visibility and rasterization later.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself       | Can you explain how 'Orthographic Projection 3/4' changes positions before rasterization?                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Page 48                     | Orthographic Projection 4/4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Source cue                  | - Multiplication of all orthographic projection matrices results in $2 \ r + l / 0$<br>$0 - / r - l \ r - l / 2 \ t + b$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Orthographic Projection 4/4' explains how camera geometry turns a 3D scene into image coordinates. In view space, objects are described relative to the camera. The projection matrix then maps that camera-centered geometry into clip space, where the viewing volume and clipping boundaries can be handled consistently. Perspective projection uses the homogeneous coordinate so that the later divide by w creates foreshortening: farther objects occupy less image space. Orthographic projection removes that depth-based size change and keeps parallel structures visually parallel. The terms describe camera-to-screen mapping: - Multiplication of all orthographic projection matrices results in $2 \ r + l / 0 \ 0 - / r - l \ r - l / 2 \ t + b$ . View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport. The object chain is view-space position, projection matrix, clip coordinate, normalized device coordinate, and viewport coordinate. The slide is therefore connecting camera setup, visual appearance, and the numeric coordinate pipeline that rasterization later consumes. |
| Technical commentary        | This slide is about Orthographic Projection 4/4. The projection objects on the slide convert view-space geometry into clip coordinates, normalized coordinates, and finally screen-related positions. The terms describe camera-to-screen mapping: - Multiplication of all orthographic projection matrices results in $2 \ r + l / 0 \ 0 - / r - l \ r - l / 2 \ t + b$ . View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Why it matters              | Projection controls both image composition and depth precision, so it affects visibility and rasterization later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you explain how 'Orthographic Projection 4/4' changes positions before rasterization?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide '4.6 Perspective Projection Derivation' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: Step-wise transformation of a frustum into a cube. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about 4.6 Perspective Projection Derivation. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: Step-wise transformation of a frustum into a cube. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you state the coordinate space before and after '4.6 Perspective Projection Derivation'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Page 50                     | Perspective Projection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Source cue                  | - Transform view volume created by <code>glm::frustum</code> or <code>glm::perspective</code> into / canonical view volume / and then create the projected image by neglecting z-values / (1, 1, 1) / (-1,-1,-1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Professor-style explanation | The slide 'Perspective Projection' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Transform view volume created by <code>glm::frustum</code> or <code>glm::perspective</code> into / canonical view volume / and then create the projected image by neglecting z-values / (1, 1, 1) / (-1,-1,-1). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |

|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Perspective Projection. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Transform view volume created by <code>glm::frustum</code> or <code>glm::perspective</code> into / canonical view volume / and then create the projected image by neglecting z-values / (1, 1, 1) / (-1,-1,-1). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. |
| Why it matters       | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself       | Can you state the coordinate space before and after 'Perspective Projection'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | The slide 'Transformation of z-Values 1/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - After the perspective projection, z-values shall be mapped as follows / - All z-values lying on the near plane shall have a value of -1 / - All z-values lying on the far plane shall have a value of 1 / - The following matrix P allows modification of the depth values / and assures the flip (left-handed to right-handed conversion). Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |

Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Check yourself              | Can you state the coordinate space before and after 'Transformation of z-Values 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Page 52                     | Transformation of z-Values 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Source cue                  | - Choosing values for a and b in $P / -a \text{ and } b$ must fulfill the following $/ -an + b / P \cdot 0 \ 0 \ -n \ 1 \ T = 0 \ 0 \ -an + b \ n \ T \ 0 \ 0 = 0 \ 0 \ -1 / \div w \ n$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | The slide 'Transformation of z-Values 2/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Choosing values for a and b in $P / -a \text{ and } b$ must fulfill the following $/ -an + b / P \cdot 0 \ 0 \ -n \ 1 \ T = 0 \ 0 \ -an + b \ n \ T \ 0 \ 0 = 0 \ 0 \ -1 / \div w \ n$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Transformation of z-Values 2/2. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Choosing values for a and b in $P / -a \text{ and } b$ must fulfill the following $/ -an + b / P \cdot 0 \ 0 \ -n \ 1 \ T = 0 \ 0 \ -an + b \ n \ T \ 0 \ 0 = 0 \ 0 \ -1 / \div w \ n$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you state the coordinate space before and after 'Transformation of z-Values 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Page 53                     | Transformation of x- and y-Values 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Source cue                  | - Derivation so far leaves us with the following matrix $/$ which only changes z-coordinates $/ 1 \ 0 \ 0 \ 0 / 0 \ 1 \ 0 \ 0 / - P = f+n \ 2nf$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | The slide 'Transformation of x- and y-Values 1/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Derivation so far leaves us with the following matrix / which only changes z-coordinates / $\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$ / $P = f+n \cdot 2n$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Transformation of x- and y-Values 1/2. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Derivation so far leaves us with the following matrix / which only changes z-coordinates / $\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$ / $P = f+n \cdot 2n$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you state the coordinate space before and after 'Transformation of x- and y-Values 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Page 54                     | Transformation of x- and y-Values 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Source cue                  | - To transform p to the coordinates (1,0,-1), the following equation must hold / $\alpha \tan / \alpha n \cdot \tan / n \cdot \tan 2 / 2 \cdot 1$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Professor-style explanation | The slide 'Transformation of x- and y-Values 2/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - To transform p to the coordinates (1,0,-1), the following equation must hold / $\alpha \tan / \alpha n \cdot \tan / n \cdot \tan 2 / 2 \cdot 1$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear.                                |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Source cue                  | Mapping the normalized device coordinates to the screen                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide '4.7 Viewport Transformation' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: Mapping the normalized device coordinates to the screen. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about 4.7 Viewport Transformation. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: Mapping the normalized device coordinates to the screen. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | <p>The slide 'Screen Coordinate Mapping' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion:</p> <ul style="list-style-type: none"> <li>- Mapping of the viewing plane on a drawing surface</li> <li>- Define the pixel rectangle to be mapped to</li> <li>- Initially, this rectangle is the size of the entire canvas</li> <li>- <code>glViewport(GLint x, GLint y, GLsizei width, GLsizei height)</code></li> <li>- When window size changes, adjust the aspect ratio to avoid distortion. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear.</li> </ul> |
| Technical commentary        | <p>This slide is about Screen Coordinate Mapping. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion:</p> <ul style="list-style-type: none"> <li>- Mapping of the viewing plane on a drawing surface</li> <li>- Define the pixel rectangle to be mapped to</li> <li>- Initially, this rectangle is the size of the entire canvas</li> <li>- <code>glViewport(GLint x, GLint y, GLsizei width, GLsizei height)</code></li> <li>- When window size changes, adjust the aspect ratio to avoid distortion. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you state the coordinate space before and after 'Screen Coordinate Mapping'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | The slide 'Viewport Transformation 1/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Specification of the viewport parameters by glm::perspective / Projection / glm::frustum / transformation / - glViewport(x, y, w, h) glm::ortho. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear.                                               |
| Technical commentary        | This slide is about Viewport Transformation 1/2. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Specification of the viewport parameters by glm::perspective / Projection / glm::frustum / transformation / - glViewport(x, y, w, h) glm::ortho. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you state the coordinate space before and after 'Viewport Transformation 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Page 58                     | Viewport Transformation 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source cue                  | - Viewport transformation is a 2D transformation defined as $p = M \cdot p$ with $s \cdot N / \Delta x \Delta y / - M = T \cdot x, y \cdot S \cdot S, S \cdot T -x, -y / s$ Smin Smin Nmin Nmin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Viewport Transformation 2/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Viewport transformation is a 2D transformation defined as $p = M \cdot p$ with $s \cdot N / \Delta x \Delta y / - M = T \cdot x, y \cdot S \cdot S, S \cdot T -x, -y / s$ Smin Smin Nmin Nmin. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |

| Technical commentary | This slide is about Viewport Transformation 2/2. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Viewport transformation is a 2D transformation defined as $p = M \cdot p$ with $/s \leq N / \Delta x \Delta y / - M = T x, y \cdot S S, S \cdot T -x, -y / s$ $S_{min} S_{min} N_{min} N_{min}$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. |
| Why it matters       | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself       | Can you state the coordinate space before and after 'Viewport Transformation 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | The slide 'volume, we can differentiate different projection types' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Projection has its origins in the arts / - Based on the deformation of the initial view volume to the canonical view / volume, we can differentiate different projection types / - In OpenGL two main projection types exist / - Perspective projection results in perspective shortening. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about volume, we can differentiate different projection types. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Projection has its origins in the arts / - Based on the deformation of the initial view volume to the canonical view / volume, we can differentiate different projection types / - In OpenGL two main projection types exist / - Perspective projection results in perspective shortening. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'volume, we can differentiate different projection types'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Source cue                  | No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Literature and other sources used in this chapter' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail.                                                                                                 |
| Technical commentary        | This slide is about Literature and other sources used in this chapter. The slide lists source material or chapter references that support the technical content and give names for further reading. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                                                                                                                              |
| Why it matters              | Reference slides provide the source trail for definitions, algorithms, and deeper explanations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you identify which source or topic 'Literature and other sources used in this chapter' points to for deeper study?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Page 61                     | - Text Books                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Marschner: Fundamentals of Computer Graphics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Professor-style explanation | The slide '- Text Books' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - J. Foley, A. van Dam, S. Feiner: Computer Graphics: Principles and Practice (3rd / - P. Shirley, M. Ashikhmin, S. Marschner: Fundamentals of Computer Graphics. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about - Text Books. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - J. Foley, A. van Dam, S. Feiner: Computer Graphics: Principles and Practice (3rd / - P. Shirley, M. Ashikhmin, S. Marschner: Fundamentals of Computer Graphics. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 04.1 Linear Perspective and Planar Projections

Source location: Sections 4.1-4.2

### Commentary

Perspective projection models the visual effect that farther objects appear smaller. Orthographic projection removes this distance-based size change and keeps parallel lines parallel. Both are useful, but they communicate different spatial relationships.

Planar projection means mapping points onto an image plane. The lecture's art examples are not decoration; they show that projection is a geometric rule for constructing an image from a viewpoint.

### Mental model

Projection is the rule that turns 3D positions into image-plane positions.

### Check yourself

What visual cue does perspective projection add that orthographic projection lacks?

## 04.2 Camera Modeling

Source location: Section 4.3

### Commentary

A virtual camera is defined by position, orientation, projection type, viewing volume, and image/viewport settings. The view transform places the world relative to the camera. The projection transform maps that view into clip coordinates.

Near and far clipping planes are part of the camera model. They decide what range of depths is represented and strongly affect depth buffer precision. A careless near/far setup can create z-fighting even if the scene geometry is correct.

### Mental model

A camera is not only an eye position; it is also a volume and a mapping rule.

### Check yourself

Why can changing the near plane affect depth artifacts?

## 04.3 Specifying Projections in OpenGL

Source location: Section 4.4

### Commentary

In OpenGL, projection is usually encoded in a projection matrix sent to a shader. The matrix maps view-space coordinates to clip space. Clipping and the perspective divide then lead toward normalized device coordinates.

Aspect ratio and field of view must match the intended viewport. If the aspect ratio is wrong, objects appear stretched. If the field of view is extreme, the image can look distorted even though the math is functioning.

## **Mental model**

The projection matrix is the camera lens encoded as linear algebra in homogeneous coordinates.

## **Check yourself**

What symptom suggests that the projection aspect ratio does not match the window?

# **04.4 Orthographic and Perspective Derivations**

Source location: Sections 4.5-4.6

## **Commentary**

The derivations are there to explain where the matrix entries come from. Orthographic projection maps a box-shaped view volume into normalized coordinates. Perspective projection maps a frustum and uses the homogeneous component for the later divide.

You do not need to treat these matrices as random formulas. Each part maps a coordinate range into a standard range. The perspective matrix additionally arranges  $w$  so that the perspective divide creates foreshortening.

## **Mental model**

Projection matrices normalize a viewing volume; perspective also prepares the divide by  $w$ .

## **Check yourself**

What does the perspective divide do to  $x$  and  $y$  coordinates?

# **04.5 Viewport Transformation**

Source location: Section 4.7

## **Commentary**

After normalized device coordinates, the viewport transform maps the normalized range to actual window coordinates. This is the last geometric mapping before rasterization uses the target grid.

Separating projection from viewport mapping helps debugging. A wrong projection can produce wrong normalized coordinates; a wrong viewport can map otherwise valid coordinates into the wrong part of the window.

## **Mental model**

Projection decides normalized position; viewport decides where that position lands on the screen.

## **Check yourself**

Why is resizing a window related to both viewport and projection settings?

# **End-of-lecture summary**

If you remember only one thing from Lecture 04, remember this: This lecture explains how a 3D view becomes a 2D image. Projection is where camera geometry, homogeneous coordinates, clipping planes, depth precision, and viewport mapping meet.

Before moving on, you should be able to explain the lecture without reading slide bullets aloud. Use the vocabulary from the slides, but add causal links: why a step exists, what data it consumes, what it produces, and what can go wrong.

# Lecture 05 - Clipping

This lecture focuses on algorithms that remove or trim geometry against boundaries. Clipping is a geometric operation before rasterization, not a visibility test between overlapping objects.

## How to read this lecture

- Read the section commentary before looking at the raw slide bullets.
- Use the mental model as the short version you should remember.
- Answer the check question without notes before continuing.

## Per-slide commentary

Each extracted slide page gets its own note. Use this section as the spoken commentary that the terse slide deck is missing.

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Source cue                  | No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Professor-style explanation | The slide 'Visual or title slide' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail. |
| Technical commentary        | This slide is about Visual or title slide. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                              |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you turn 'Visual or title slide' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 2                      | Clipping Projected Geometry 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Source cue                  | - Now that the geometry has been transformed to its representation on the / screen, parts outside screen must be clipped away / - Clipping ensures that following costly computations / (e.g., rasterization, illumination, shading) are only applied to visible parts / - Since clipping is performed for all geometry, algorithms are highly optimized                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | The slide 'Clipping Projected Geometry 1/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Now that the geometry has been transformed to its representation on the / screen, parts outside screen must be clipped away / - Clipping ensures that following costly computations / (e.g., rasterization, illumination, shading) are only applied to visible parts / - Since clipping is performed for all geometry, algorithms are highly optimized. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Clipping Projected Geometry 1/2. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Now that the geometry has been transformed to its representation on the / screen, parts outside screen must be clipped away / - Clipping ensures that following costly computations / (e.g., rasterization, illumination, shading) are only applied to visible parts / - Since clipping is performed for all geometry, algorithms are highly optimized. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you state the coordinate space before and after 'Clipping Projected Geometry 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Clipping Projected Geometry 2/2' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Analytical clipping / - Clipping before raster conversion, clipped primitives are raster-converted / - Compute time savings if clipped primitive is much smaller than unclipped / - OpenGL: clipping against canonical view volume / - Pixel-based clipping. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.</p> |
| Technical commentary        | <p>This slide is about Clipping Projected Geometry 2/2. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Analytical clipping / - Clipping before raster conversion, clipped primitives are raster-converted / - Compute time savings if clipped primitive is much smaller than unclipped / - OpenGL: clipping against canonical view volume / - Pixel-based clipping. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | <p>OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | <p>Can you name the OpenGL object, state, shader stage, or buffer involved in 'Clipping Projected Geometry 2/2'?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 4                      | 5.1 Cohen-Sutherland Line Clipping                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide '5.1 Cohen-Sutherland Line Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: 5.2 Cyrus-Beck Line Clipping / 5.3 Sutherland-Hodgman Polygon Clipping / 5.4 Weiler-Atherton Polygon Clipping / 5.5 Greiner-Hormann Polygon Clipping. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.</p>                                                                                                                                                                                                                                                          |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Technical commentary | This slide is about 5.1 Cohen-Sutherland Line Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: 5.2 Cyrus-Beck Line Clipping / 5.3 Sutherland-Hodgman Polygon Clipping / 5.4 Weiler-Atherton Polygon Clipping / 5.5 Greiner-Hormann Polygon Clipping. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. |
| Why it matters       | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself       | Can you decide what is accepted, rejected, or newly intersected in '5.1 Cohen-Sutherland Line Clipping'?                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Source cue                  | Clip lines against rectangle                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | The slide '5.1 Cohen-Sutherland Line Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: Clip lines against rectangle. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about 5.1 Cohen-Sutherland Line Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: Clip lines against rectangle. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | The slide 'Brute-Force Line Clipping 1/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Check each edge of the rectangle for intersection with line / - Intersection calculation for the line defined by the edge, and the line / - If intersection lies within edge and within line, clipping necessary. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |

The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Check each edge of the rectangle for intersection with line / - Intersection calculation for the line defined by the edge, and the line / - If intersection lies within edge and within line, clipping necessary. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Brute-Force Line Clipping 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide 'Brute-Force Line Clipping 2/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Using the parameter representation for lines $x - x_0 = t(x_1 - x_0)$ / $p = p_0 + t(p_1 - p_0)$ , $p_0 = x_0, y_0$ / $p_1 = x_1, y_1$ . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Brute-Force Line Clipping 2/2. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Using the parameter representation for lines $x - x_0 = t(x_1 - x_0)$ / $p = p_0 + t(p_1 - p_0)$ , $p_0 = x_0, y_0$ / $p_1 = x_1, y_1$ . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Endpoint Analysis 1/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Idea: Use end point analysis to create new lines / - Clipping against a rectangle yields a line / - Clipping against a convex polygon results in a line / - Endpoint analysis / - Line segment $s = (p, p)$ , $p = (x, y)$ and $p = (x, y)$ . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Endpoint Analysis 1/2. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Idea: Use end point analysis to create new lines / - Clipping against a rectangle yields a line / - Clipping against a convex polygon results in a line / - Endpoint analysis / - Line segment $s = (p, p)$ , $p = (x, y)$ and $p = (x, y)$ . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Endpoint Analysis 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | The slide 'Endpoint Analysis 2/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Clipping lines against a clip rectangle by reduction to endpoint analysis / - If both endpoints are to the right of x and to the left of x / min max / and above y and below y , they are inside / min max. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Endpoint Analysis 2/2. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Clipping lines against a clip rectangle by reduction to endpoint analysis / - If both endpoints are to the right of x and to the left of x / min max / and above y and below y , they are inside / min max. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Endpoint Analysis 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | The slide 'Binary Coding of Half-Planes 1/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Classification of the plane in nine regions / - Classify a point by one bit each / for belonging to each of the 4 half-planes / 1001 1000 1010 / - 4-bit outcode. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Binary Coding of Half-Planes 1/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Classification of the plane in nine regions / - Classify a point by one bit each / for belonging to each of the 4 half-planes / 1001 1000 1010 / - 4-bit outcode. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you turn 'Binary Coding of Half-Planes 1/3' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Page 11                     | Binary Coding of Half-Planes 2/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Source cue                  | - Endpoint classification / - Line segment $s = (p, p) / 0 1$ / - Outcodes: / 1001 1000 1010                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Binary Coding of Half-Planes 2/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Endpoint classification / - Line segment $s = (p, p) / 0 1$ / - Outcodes: / 1001 1000 1010. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Binary Coding of Half-Planes 2/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Endpoint classification / - Line segment $s = (p, p) / 0 1$ / - Outcodes: / 1001 1000 1010. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you explain which samples/fragments are generated by 'Binary Coding of Half-Planes 2/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Page 12                     | Binary Coding of Half-Planes 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | The slide 'Binary Coding of Half-Planes 3/3' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Clipping, if $(oc0 \& oc1) = 0$ : / - Choose an order for clipping (e.g., top, bottom, right, left) / - Select clip edge that is crossed by the line / - Check done on basis of bit codes, which differ in at least 1 bit / - Clip s at this clip edge. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Binary Coding of Half-Planes 3/3. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Clipping, if $(oc0 \& oc1) = 0$ : / - Choose an order for clipping (e.g., top, bottom, right, left) / - Select clip edge that is crossed by the line / - Check done on basis of bit codes, which differ in at least 1 bit / - Clip s at this clip edge. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | The slide 'Pseudo Code' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: void cohensutherlandLineClipper(Line s, Rectangle r) { / int oc0 = outcode(s.p0, r); / int oc1 = outcode(s.p1, r); / bool done = false; / while (!done) { int outcode(Point p, Rectangle r) {. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Pseudo Code. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: void cohensutherlandLineClipper(Line s, Rectangle r) { / int oc0 = outcode(s.p0, r); / int oc1 = outcode(s.p1, r); / bool done = false; / while (!done) { int outcode(Point p, Rectangle r) {. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. |
| Why it matters       | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself       | Can you decide what is accepted, rejected, or newly intersected in 'Pseudo Code'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Page 14                     | Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Source cue                  | 1001 1000 1010 / 0001 0000 0010 / 0101 0100 0110                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Professor-style explanation | The slide 'Example' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: 1001 1000 1010 / 0001 0000 0010 / 0101 0100 0110. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Example. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: 1001 1000 1010 / 0001 0000 0010 / 0101 0100 0110. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you turn 'Example' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide 'Evaluation' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Occasionally performs several (unnecessary) clip operations on a line as test / and clippings are done in a fixed edge order / - Especially efficient when / - almost all lines are outside / - almost all lines are inside. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Evaluation. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Occasionally performs several (unnecessary) clip operations on a line as test / and clippings are done in a fixed edge order / - Especially efficient when / - almost all lines are outside / - almost all lines are inside. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Evaluation'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide '5.2 Cyrus-Beck Line Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: Clip lines against convex polygon. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.                                                                                                                                                                           |
| Technical commentary        | This slide is about 5.2 Cyrus-Beck Line Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: Clip lines against convex polygon. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | The slide 'Cyrus-Beck Line Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Introduced in 1978 by Cyrus and Beck / - Algorithm for clipping lines against a convex polygon in the plane / - Expandable to clipping lines against a convex polyhedron in space / - Fundamentally different approach than Cohen-Sutherland / - Further development in 1984 by Liang and Barsky. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Cyrus-Beck Line Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Introduced in 1978 by Cyrus and Beck / - Algorithm for clipping lines against a convex polygon in the plane / - Expandable to clipping lines against a convex polyhedron in space / - Fundamentally different approach than Cohen-Sutherland / - Further development in 1984 by Liang and Barsky. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Parametric Line Representation' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Parametric line representation written as follows <math>p(t) = p + t \cdot p - p</math>, <math>0 \leq t \leq 1</math> / 0 1 0 / - Proceeding / - Find the 4 t's for the 4 clip edges. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Parametric Line Representation. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Parametric line representation written as follows <math>p(t) = p + t \cdot p - p</math>, <math>0 \leq t \leq 1</math> / 0 1 0 / - Proceeding / - Find the 4 t's for the 4 clip edges. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | <p>The slide 'Intersection Point Calculation 1/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Consider edge E and its outward pointing edge normal N / - Through dot product <math>N \cdot (p(t) - p)</math> it can be decided / in which half-space a line point p(t) lies / <math>N \cdot (p(t) - p) &lt; 0</math> / E E. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |

| Technical commentary | This slide is about Intersection Point Calculation 1/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Consider edge E and its outward pointing edge normal N / - Through dot product $N \cdot (p(t) - p)$ it can be decided / in which half-space a line point p(t) lies / $N \cdot (p(t) - p) < 0$ / E. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself       | Can you explain which samples/fragments are generated by 'Intersection Point Calculation 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Page 20                     | Intersection Point Calculation 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Source cue                  | - Determine intersection by calculating t for $N \cdot p \cdot t - p = 0$ / - Substitution of p t and regrouping gives $N \cdot p - p / 0$ E                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Professor-style explanation | The slide 'Intersection Point Calculation 2/2' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Determine intersection by calculating t for $N \cdot p \cdot t - p = 0$ / - Substitution of p t and regrouping gives $N \cdot p - p / 0$ E. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Intersection Point Calculation 2/2. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Determine intersection by calculating t for $N \cdot p \cdot t - p = 0$ / - Substitution of p t and regrouping gives $N \cdot p - p / 0$ E. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you turn 'Intersection Point Calculation 2/2' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

The terms form an input-operation-output relation: - Classification of intersection points as potentially entering (PE) / or potentially leaving (PL) with respect to interior of half-plane edge / s PE / PL PL PL / p s. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you turn 'Determine Relevant t-Values' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Page 22                     | Pseudo Code                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Source cue                  | <code>void cyrusBeckLineClipper(Line s, Rectangle r) { / precalculate N for edges of r and select P / i E / D = s.p1 - s.p0 / if (s.p0 == s.p1) {</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Professor-style explanation | The slide 'Pseudo Code' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: <code>void cyrusBeckLineClipper(Line s, Rectangle r) { / precalculate N for edges of r and select P / i E / D = s.p1 - s.p0 / if (s.p0 == s.p1) {</code> . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Pseudo Code. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: <code>void cyrusBeckLineClipper(Line s, Rectangle r) { / precalculate N for edges of r and select P / i E / D = s.p1 - s.p0 / if (s.p0 == s.p1) {</code> . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Pseudo Code'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Page 23                     | Axis-Parallel Clipping Region                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Source cue                  | - When clipping region is axis parallel and given by $[x_{min}, x_{max}] \times [y_{min}, y_{max}]$ , / min max min max / following values occur / $N \cdot p - p / 0 \ E$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Axis-Parallel Clipping Region' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - When clipping region is axis parallel and given by $[x_{min}, x_{max}] \times [y_{min}, y_{max}]$ , / min max min max / following values occur / $N \cdot p - p / 0 \ E$ . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Axis-Parallel Clipping Region. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - When clipping region is axis parallel and given by $[x_{min}, x_{max}] \times [y_{min}, y_{max}]$ , / min max min max / following values occur / $N \cdot p - p / 0 \ E$ . A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Axis-Parallel Clipping Region'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Professor-style explanation | <p>The slide 'Comparison with Cohen-Sutherland' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Algorithm of Cohen-Sutherland / - Sometimes performs useless clip operations, / as clipping and testing are done in a fixed order / - Efficient when outcode tests can be performed inexpensively (e.g., by bitwise / operations) and the majority of line segments are trivially accepted or rejected. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.</p> |
| Technical commentary        | <p>This slide is about Comparison with Cohen-Sutherland. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Algorithm of Cohen-Sutherland / - Sometimes performs useless clip operations, / as clipping and testing are done in a fixed order / - Efficient when outcode tests can be performed inexpensively (e.g., by bitwise / operations) and the majority of line segments are trivially accepted or rejected. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | <p>The slide '5.3 Sutherland-Hodgman Polygon Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: A pipelined version of the scalar product algorithm extended to clip polygons. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.</p>                                                                                                                                                                                                                     |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Technical commentary | This slide is about 5.3 Sutherland-Hodgman Polygon Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: A pipelined version of the scalar product algorithm extended to clip polygons. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. |
| Why it matters       | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                            |

| Page 26                     | Sutherland-Hodgman Polygon Clipping 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Source cue                  | - Background / - General polygon clipping (arbitrary polygon against convex polygon) / - Originally developed for visibility detection / (apply before rasterization to eliminate non-visible polygon pieces) / - Polygon clipping is more complex than line clipping                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Professor-style explanation | The slide 'Sutherland-Hodgman Polygon Clipping 1/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Background / - General polygon clipping (arbitrary polygon against convex polygon) / - Originally developed for visibility detection / (apply before rasterization to eliminate non-visible polygon pieces) / - Polygon clipping is more complex than line clipping. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Sutherland-Hodgman Polygon Clipping 1/2. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Background / - General polygon clipping (arbitrary polygon against convex polygon) / - Originally developed for visibility detection / (apply before rasterization to eliminate non-visible polygon pieces) / - Polygon clipping is more complex than line clipping. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | The slide 'Sutherland-Hodgman Polygon Clipping 2/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Iterative algorithm paradigm / - Clipping a polygon takes place against a half-plane / - Clipping is performed sequentially for each edge of the clipping region / - Input / - Convex clipping region. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Sutherland-Hodgman Polygon Clipping 2/2. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Iterative algorithm paradigm / - Clipping a polygon takes place against a half-plane / - Clipping is performed sequentially for each edge of the clipping region / - Input / - Convex clipping region. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Sutherland-Hodgman Polygon Clipping 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Page 28                     | Four Cases                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Source cue                  | - Depending on which case occurs, following points added to output list / - Case 1: p / - Case 2: Intersection point i / - Case 3: -- / - Case 4: Intersection point i and p                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | The slide 'Four Cases' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Depending on which case occurs, following points added to output list / - Case 1: p / - Case 2: Intersection point i / - Case 3: -- / - Case 4: Intersection point i and p. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                                                                      |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Four Cases. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Depending on which case occurs, following points added to output list / - Case 1: p / - Case 2: Intersection point i / - Case 3: -- / - Case 4: Intersection point i and p. The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Check yourself       | Can you turn 'Four Cases' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Page 29                     | Proceeding                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Source cue                  | - Polygon to be clipped is defined by / - Vertices: $[v_1, v_2, \dots, v_n]$ / - Contour: $[v_1, v_2, \dots, v_n, v_1]$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Proceeding' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Polygon to be clipped is defined by / - Vertices: $[v_1, v_2, \dots, v_n]$ / - Contour: $[v_1, v_2, \dots, v_n, v_1]$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Proceeding. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Polygon to be clipped is defined by / - Vertices: $[v_1, v_2, \dots, v_n]$ / - Contour: $[v_1, v_2, \dots, v_n, v_1]$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you turn 'Proceeding' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|            |                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | The slide 'Pipeline Version' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Speed can be optimized through pipeline version / - Input: sequence of polygon vertices processed by "Pipeline of Clippers" / - Passing on to the next level once a new vertex has been identified / - No cache is needed during clipping / - Suitable for implementation by hardware. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Pipeline Version. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Speed can be optimized through pipeline version / - Input: sequence of polygon vertices processed by "Pipeline of Clippers" / - Passing on to the next level once a new vertex has been identified / - No cache is needed during clipping / - Suitable for implementation by hardware. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Pipeline Version'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Page 31                     | Pseudo Code                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Source cue                  | <pre> public VertexList shClipper(VertexList inputVertices, Edge clipE) { / VertexList outputVertices; // output list of vertices / int N = inputVertices.size(); // number of vertices to be processed / Vertex s = inputVertices.get(N-1); // get last vertex / for (int j = 0; j &lt; N; j++) { </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Pseudo Code' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: public VertexList shClipper(VertexList inputVertices, Edge clipE) { / VertexList outputVertices; // output list of vertices / int N = inputVertices.size(); // number of vertices to be processed / Vertex s = inputVertices.get(N-1); // get last vertex / for (int j = 0; j < N; j++) {. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Technical commentary | This slide is about Pseudo Code. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: <code>public VertexList shClipper(VertexList inputVertices, Edge clipE) { / VertexList outputVertices; // output list of vertices / int N = inputVertices.size(); // number of vertices to be processed / Vertex s = inputVertices.get(N-1); // get last vertex / for (int j = 0; j &lt; N; j++) {</code> . The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself       | Can you turn 'Pseudo Code' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Source cue                  | - Inside test for rectangular clip regions / <code>boolean inside(Vertex v, Edge e) { // e is edge of a clip rectangle / if (e.v1.x &gt; e.v0.x) // bottom / if (v.y &gt;= e.v0.y) return true; / else if (e.v1.x &lt; e.v0.x) // top</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Professor-style explanation | The slide 'Inside Test' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Inside test for rectangular clip regions / <code>boolean inside(Vertex v, Edge e) { // e is edge of a clip rectangle / if (e.v1.x &gt; e.v0.x) // bottom / if (v.y &gt;= e.v0.y) return true; / else if (e.v1.x &lt; e.v0.x) // top</code> . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Inside Test. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Inside test for rectangular clip regions / <code>boolean inside(Vertex v, Edge e) { // e is edge of a clip rectangle / if (e.v1.x &gt; e.v0.x) // bottom / if (v.y &gt;= e.v0.y) return true; / else if (e.v1.x &lt; e.v0.x) // top</code> . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Intersection Computation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - For rectangular clip regions / Vertex intersect(Vertex p, Vertex s, Edge e) { / Vertex i; / if (e.v0.y == e.v1.y) { // horizontal edge / i.y = e.v0.y. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Intersection Computation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - For rectangular clip regions / Vertex intersect(Vertex p, Vertex s, Edge e) { / Vertex i; / if (e.v0.y == e.v1.y) { // horizontal edge / i.y = e.v0.y. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you turn 'Intersection Computation' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Source cue                  | Clip arbitrary polygons against arbitrary clip polygons                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Professor-style explanation | The slide '5.4 Weiler-Atherton Polygon Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: Clip arbitrary polygons against arbitrary clip polygons. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about 5.4 Weiler-Atherton Polygon Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: Clip arbitrary polygons against arbitrary clip polygons. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in '5.4 Weiler-Atherton Polygon Clipping'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide 'Weiler-Atherton Polygon Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Basic idea: edges of the clip polygon A and the polygon B to be clipped / divide the plane into disjoint regions / - Following four region types are distinguished / 1. Only-in-A (light blue) / 2. Only-in-B (gray). A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Weiler-Atherton Polygon Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Basic idea: edges of the clip polygon A and the polygon B to be clipped / divide the plane into disjoint regions / - Following four region types are distinguished / 1. Only-in-A (light blue) / 2. Only-in-B (gray). A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Weiler-Atherton Polygon Clipping'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Page 36                     | Example Run                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Source cue                  | - Proceeding best illustrated by example run / - Given case: two partially overlapping polygons / - Insert all intersections of A and B / - Double all edge segments, and label each segment / according to the adjacent region                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Professor-style explanation | The slide 'Example Run' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Proceeding best illustrated by example run / - Given case: two partially overlapping polygons / - Insert all intersections of A and B / - Double all edge segments, and label each segment / according to the adjacent region. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                          |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Technical commentary | This slide is about Example Run. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Proceeding best illustrated by example run / - Given case: two partially overlapping polygons / - Insert all intersections of A and B / - Double all edge segments, and label each segment / according to the adjacent region. The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself       | Can you turn 'Example Run' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Page 37                     | Intersection Types                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source cue                  | - There are two intersection types that are distinguished / - Transversal intersections / - Two edges of the two polygons intersect at one point / - Procedure: intersection is inserted in vertex list of both polygons / - Segment overlaps (non-transversal)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Professor-style explanation | The slide 'Intersection Types' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - There are two intersection types that are distinguished / - Transversal intersections / - Two edges of the two polygons intersect at one point / - Procedure: intersection is inserted in vertex list of both polygons / - Segment overlaps (non-transversal). The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Intersection Types. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - There are two intersection types that are distinguished / - Transversal intersections / - Two edges of the two polygons intersect at one point / - Procedure: intersection is inserted in vertex list of both polygons / - Segment overlaps (non-transversal). The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you turn 'Intersection Types' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | The slide 'Evaluation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Extension to multiple polygons / - Efficiently possible through iterative application / - Alternatively, intersection points can be generated / for all polygons in in the first step / - Conclusion. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Evaluation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Extension to multiple polygons / - Efficiently possible through iterative application / - Alternatively, intersection points can be generated / for all polygons in in the first step / - Conclusion. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you turn 'Evaluation' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Page 40                     | 5.5 Greiner-Hormann Polygon Clipping                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide '5.5 Greiner-Hormann Polygon Clipping' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: Exploitation of the winding number to clip arbitrary polygons. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.                                                                    |
| Technical commentary        | This slide is about 5.5 Greiner-Hormann Polygon Clipping. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: Exploitation of the winding number to clip arbitrary polygons. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in '5.5 Greiner-Hormann Polygon Clipping'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Page 41                     | Greiner-Hormann                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Source cue                  | - Basic Idea: clipped region is made up of all edges of S that lie in C, / combined with all edges of C that lie in S / [Greiner & Hormann, TOG 1998]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Professor-style explanation | The slide 'Greiner-Hormann' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Basic Idea: clipped region is made up of all edges of S that lie in C, / combined with all edges of C that lie in S / [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Greiner-Hormann. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Basic Idea: clipped region is made up of all edges of S that lie in C, / combined with all edges of C that lie in S / [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. |
| Why it matters       | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Chalk Wagon Metaphor' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Using a chalk wagon metaphor / - Drive along all edges of A with a chalk wagon / that is only open when the current position is within B / - Drive along all edges of B with a chalk wagon / that is only open when the current position is within A. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Chalk Wagon Metaphor. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Using a chalk wagon metaphor / - Drive along all edges of A with a chalk wagon / that is only open when the current position is within B / - Drive along all edges of B with a chalk wagon / that is only open when the current position is within A. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you turn 'Chalk Wagon Metaphor' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|            |                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Contour Detection' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - The edges of polygon A within polygon B can thus be found as follows / - Insert in A all intersection points with B / - Start at any vertex v of A / - If v is within B, the edge flag is turned on, otherwise not / - Traverse edges of A and invert edge marker flag when intersecting with B. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Contour Detection. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - The edges of polygon A within polygon B can thus be found as follows / - Insert in A all intersection points with B / - Start at any vertex v of A / - If v is within B, the edge flag is turned on, otherwise not / - Traverse edges of A and invert edge marker flag when intersecting with B. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you turn 'Contour Detection' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Page 44                     | Set Operations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide 'Set Operations' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.                                                                                                                           |
| Technical commentary        | This slide is about Set Operations. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Data Structure 1/2' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Polygons exist as a closed, double-linked list / $P, P, P, \dots, P = P / 0 \ 1 \ 2 \ n \ 0$ / - The following segments are included / $P \ P, P \ P, \dots, P \ P = P \ P$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Data Structure 1/2. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Polygons exist as a closed, double-linked list / $P, P, P, \dots, P = P / 0 \ 1 \ 2 \ n \ 0$ / - The following segments are included / $P \ P, P \ P, \dots, P \ P = P \ P$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you turn 'Data Structure 1/2' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Page 46                     | Data Structure 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Source cue                  | [Greiner & Hormann, TOG 1998]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Professor-style explanation | The slide 'Data Structure 2/2' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.     |
| Technical commentary        | This slide is about Data Structure 2/2. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Data Structure 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Page 47                     | Proceeding                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | - Create data structure / - Create doubly linked list with node data structure / - Add the intersections with the corresponding alpha values to the list / - Traverse the polygon to find entry and exit points / (use winding number rule)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Proceeding' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Create data structure / - Create doubly linked list with node data structure / - Add the intersections with the corresponding alpha values to the list / - Traverse the polygon to find entry and exit points / (use winding number rule). The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Proceeding. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Create data structure / - Create doubly linked list with node data structure / - Add the intersections with the corresponding alpha values to the list / - Traverse the polygon to find entry and exit points / (use winding number rule). The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you turn 'Proceeding' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 48                     | Pseudo Code                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Source cue                  | while unprocessed intersections in subject polygon / current = first unprocessed intersecting / point of subject polygon / newPolygon() / newVertex(current)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | The slide 'Pseudo Code' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: while unprocessed intersections in subject polygon / current = first unprocessed intersecting / point of subject polygon / newPolygon() / newVertex(current). The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Pseudo Code. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: while unprocessed intersections in subject polygon / current = first unprocessed intersecting / point of subject polygon / newPolygon() / newVertex(current). The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you turn 'Pseudo Code' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Professor-style explanation | The slide 'Winding Number 1/3' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Winding number of a point A and a closed curve $\gamma$ / indicates the number of times a ray that traverses the entire curve from A / winds around A / $\omega \gamma$ , $A = d\phi$ / - Counterclockwise: +1. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Winding Number 1/3. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Winding number of a point A and a closed curve $\gamma$ / indicates the number of times a ray that traverses the entire curve from A / winds around A / $\omega \gamma$ , $A = d\phi$ / - Counterclockwise: +1. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you decide whether 'Winding Number 1/3' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Page 50                     | Winding Number 2/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Source cue                  | - The winding number of a point A has the following useful properties / 1. If A or the curve $\gamma$ is continuously changed so that A maintains a / positive distance to $\gamma$ , the winding number will not change / For curve $\gamma$ , the winding number is constant in each region formed by $\gamma$ / 2. When A moves and $\gamma$ crosses once, winding number changes by exactly 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Professor-style explanation | The slide 'Winding Number 2/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - The winding number of a point A has the following useful properties / 1. If A or the curve $\gamma$ is continuously changed so that A maintains a / positive distance to $\gamma$ , the winding number will not change / For curve $\gamma$ , the winding number is constant in each region formed by $\gamma$ / 2. When A moves and $\gamma$ crosses once, winding number changes by exactly 1. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Winding Number 2/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - The winding number of a point A has the following useful properties / 1. If A or the curve $\gamma$ is continuously changed so that A maintains a / positive distance to $\gamma$ , the winding number will not change / For curve $\gamma$ , the winding number is constant in each region formed by $\gamma$ / 2. When A moves and $\gamma$ crosses once, winding number changes by exactly 1. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself              | Can you turn 'Winding Number 2/3' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Page 51                     | Winding Number 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Winding Number 3/3' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - From the second property follows / - A path that cuts a curve (= the clipping polygon) just once, / runs either from inside to outside, or from outside to inside / - Clipping operation can be performed by computing / [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Winding Number 3/3. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - From the second property follows / - A path that cuts a curve (= the clipping polygon) just once, / runs either from inside to outside, or from outside to inside / - Clipping operation can be performed by computing / [Greiner & Hormann, TOG 1998]. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Winding Number 3/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 52                     | Special Cases                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Source cue                  | - Simple cases can be solved after unsuccessful intersection calculation / directly via winding number operation / - One polygon is contained in the other polygon / - Polygons have no overlaps / - Problem: One point lies on one edge                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | The slide 'Special Cases' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Simple cases can be solved after unsuccessful intersection calculation / directly via winding number operation / - One polygon is contained in the other polygon / - Polygons have no overlaps / - Problem: One point lies on one edge. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                                   |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Technical commentary | This slide is about Special Cases. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Simple cases can be solved after unsuccessful intersection calculation / directly via winding number operation / - One polygon is contained in the other polygon / - Polygons have no overlaps / - Problem: One point lies on one edge. The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself       | Can you turn 'Special Cases' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | The slide 'Evaluation' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Allows efficient clipping of arbitrary 2D polygons / - Self overlaps and holes allowed / - Idea based on definition of winding number / - Very simple and efficient implementation possible / - Much easier than Weiler-Atherton,. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Evaluation. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Allows efficient clipping of arbitrary 2D polygons / - Self overlaps and holes allowed / - Idea based on definition of winding number / - Very simple and efficient implementation possible / - Much easier than Weiler-Atherton,. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Evaluation'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Page 54                     | by exploiting binary outcodes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Source cue                  | - Cohen-Sutherland enables line clipping against rectangle / by exploiting binary outcodes / - Cyrus-Beck line clipping enables line clipping against convex polygon / by exploiting parametric representations / - Sutherland-Hodgman polygon clipping enables polygon against convex polygon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'by exploiting binary outcodes' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Cohen-Sutherland enables line clipping against rectangle / by exploiting binary outcodes / - Cyrus-Beck line clipping enables line clipping against convex polygon / by exploiting parametric representations / - Sutherland-Hodgman polygon clipping enables polygon against convex polygon. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about by exploiting binary outcodes. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Cohen-Sutherland enables line clipping against rectangle / by exploiting binary outcodes / - Cyrus-Beck line clipping enables line clipping against convex polygon / by exploiting parametric representations / - Sutherland-Hodgman polygon clipping enables polygon against convex polygon. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'by exploiting binary outcodes'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Literature and other sources used in this chapter' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail. |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | The slide 'Addison-Wesley 2013.' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Text Books / - J. Foley, A. van Dam, S. Feiner. "Computer Graphics: Principles and Practice (3rd Edition)", / Addison-Wesley 2013. / - P. Shirley, M. Ashikhmin, S. Marschner. "Fundamentals of Computer Graphics (4th / Edition)", AK Peters 2016. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Addison-Wesley 2013.. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Text Books / - J. Foley, A. van Dam, S. Feiner. "Computer Graphics: Principles and Practice (3rd Edition)", / Addison-Wesley 2013. / - P. Shirley, M. Ashikhmin, S. Marschner. "Fundamentals of Computer Graphics (4th / Edition)", AK Peters 2016. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you turn 'Addison-Wesley 2013.' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 05.1 Cohen-Sutherland Line Clipping

Source location: Section 5.1

### Commentary

Cohen-Sutherland assigns outcodes to line endpoints based on which side of the clipping window they lie on. These codes allow quick accept, quick reject, or partial clipping. The algorithm is efficient because many cases are decided before computing intersections.

The exam-friendly idea is the logic of region codes: if both endpoints are inside, keep the segment. If the bitwise AND of the outcodes is nonzero, both endpoints share an outside region and the segment can be rejected. Otherwise, compute an intersection and continue.

## **Mental model**

Outcodes are a cheap classification before doing intersection math.

## **Check yourself**

What does a nonzero bitwise AND of two endpoint outcodes imply?

# **05.2 Cyrus-Beck Line Clipping**

Source location: Section 5.2

## **Commentary**

Cyrus-Beck treats the line parametrically and clips against convex boundaries. Instead of repeatedly using region codes, it finds entering and leaving parameter values along the line.

The key is to reason about the line parameter  $t$ . A clipped line segment is not a new unrelated line; it is a restricted interval of the original parametric line. Boundary tests shrink that interval.

## **Mental model**

Clipping a parametric line means narrowing the valid  $t$  interval.

## **Check yourself**

Why does Cyrus-Beck naturally require convex clipping regions?

# **05.3 Sutherland-Hodgman Polygon Clipping**

Source location: Section 5.3

## **Commentary**

Sutherland-Hodgman clips a polygon against one boundary at a time. For each edge of the polygon, it decides whether vertices are inside or outside and emits zero, one, or two vertices depending on transitions across the boundary.

This algorithm is easiest to understand as a stream processor. Feed in a polygon, clip it against the left boundary, feed the result into the right boundary, and so on. Each boundary can add intersection vertices.

## **Mental model**

Polygon clipping is repeated edge-by-edge filtering plus intersection insertion.

## **Check yourself**

When can polygon clipping increase the number of vertices?

## 05.4 Weiler-Atherton and Greiner-Hormann

Source location: Sections 5.4-5.5

### Commentary

These algorithms address more complex polygon clipping scenarios, especially when polygon relationships are not as simple as convex-window clipping. They organize intersections and traversal rules to produce correct output boundaries.

For preparation, focus on why simpler algorithms are not enough. Complex polygon intersection can require following alternating boundaries of subject and clipping polygons. That is a topology problem, not only a line-intersection problem.

### Mental model

Complex polygon clipping is about traversing boundary networks after intersections are known.

### Check yourself

Why are intersection ordering and traversal rules important for polygon clipping?

### End-of-lecture summary

If you remember only one thing from Lecture 05, remember this: This lecture focuses on algorithms that remove or trim geometry against boundaries. Clipping is a geometric operation before rasterization, not a visibility test between overlapping objects.

Before moving on, you should be able to explain the lecture without reading slide bullets aloud. Use the vocabulary from the slides, but add causal links: why a step exists, what data it consumes, what it produces, and what can go wrong.

# Lecture 06 - Rasterization

This lecture explains how continuous primitives become discrete fragments on a grid. Rasterization is the bridge from geometric descriptions to sample-based image generation.

## How to read this lecture

- Read the section commentary before looking at the raw slide bullets.
- Use the mental model as the short version you should remember.
- Answer the check question without notes before continuing.

## Per-slide commentary

Each extracted slide page gets its own note. Use this section as the spoken commentary that the terse slide deck is missing.

| Page 1                      | Visual or title slide                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Professor-style explanation | The slide 'Visual or title slide' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail. |
| Technical commentary        | This slide is about Visual or title slide. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                              |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you turn 'Visual or title slide' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 2                      | Rasterization 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | <p>The slide 'Rasterization 1/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Pixels ... / - ... are picture elements A Pixel Is NotA Little Square, / A Pixel Is NotA Little Square, / - ... are the smallest elements of a raster image / A Pixel Is NotA Little Square!. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Rasterization 1/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Pixels ... / - ... are picture elements A Pixel Is NotA Little Square, / A Pixel Is NotA Little Square, / - ... are the smallest elements of a raster image / A Pixel Is NotA Little Square!. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide 'Rasterization 2/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Pixel-based displays require discretization of primitives into pixels / - Discretization is done by rasterization algorithms / - Rasterization is time-critical / - Avoid expensive operations / - Optimize for hardware implementation. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |

| Technical commentary | This slide is about Rasterization 2/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Pixel-based displays require discretization of primitives into pixels / - Discretization is done by rasterization algorithms / - Rasterization is time-critical / - Avoid expensive operations / - Optimize for hardware implementation. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide '6.1 Line Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: 6.2 Triangle Edge Rasterization / 6.3 Region Filling / 6.4 Scanline-Based Triangle Rasterization / 6.5 Block-Based Triangle Rasterization. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about 6.1 Line Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: 6.2 Triangle Edge Rasterization / 6.3 Region Filling / 6.4 Scanline-Based Triangle Rasterization / 6.5 Block-Based Triangle Rasterization. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself              | Can you explain which samples/fragments are generated by '6.1 Line Rasterization'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | <p>The slide '6.1 Line Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: Drawing a one pixel thick line. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about 6.1 Line Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: Drawing a one pixel thick line. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | <p>Can you explain which samples/fragments are generated by '6.1 Line Rasterization'?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | <p>The slide 'Line Rasterization' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Given two 2D endpoints in integer coordinates, / determine pixels depicting 1-pixel wide line segment between endpoints / - Trivial cases / - Horizontal line segments / - Vertical line segments. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear.</p> |

| Technical commentary | This slide is about Line Rasterization. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Given two 2D endpoints in integer coordinates, / determine pixels depicting 1-pixel wide line segment between endpoints / - Trivial cases / - Horizontal line segments / - Vertical line segments. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. |
| Why it matters       | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself       | Can you state the coordinate space before and after 'Line Rasterization'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Page 7                      | Quality Criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Source cue                  | - For all line segments with a slope $ m  \leq 1$ , / one pixel should be drawn per column / - For all line segments with a slope $ m  \geq 1$ , / one pixel per line should be drawn / $ m  > 1$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Professor-style explanation | The slide 'Quality Criteria' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - For all line segments with a slope $ m  \leq 1$ , / one pixel should be drawn per column / - For all line segments with a slope $ m  \geq 1$ , / one pixel per line should be drawn / $ m  > 1$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Quality Criteria. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - For all line segments with a slope $ m  \leq 1$ , / one pixel should be drawn per column / - For all line segments with a slope $ m  \geq 1$ , / one pixel per line should be drawn / $ m  > 1$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you explain which samples/fragments are generated by 'Quality Criteria'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Naïve Algorithm 1/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Utilization of the Cartesian normal form of the straight line equation <math>y = m \cdot x + B</math> / - Assumptions (without restriction of generality) / - Line segments lie between <math>(x, y)</math> and <math>(x, y) / 0 \leq x \leq 1</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Naïve Algorithm 1/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Utilization of the Cartesian normal form of the straight line equation <math>y = m \cdot x + B</math> / - Assumptions (without restriction of generality) / - Line segments lie between <math>(x, y)</math> and <math>(x, y) / 0 \leq x \leq 1</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | <p>Can you explain which samples/fragments are generated by 'Naïve Algorithm 1/2'?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Page 9                      | Naïve Algorithm 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | <p>The slide 'Naïve Algorithm 2/2' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Downsides / - Does not work for <math>x = x / 0 \leq x \leq 1</math> / - Does not work for <math> m  &gt; 1</math>, since gaps arise / (solution: swap the roles of <math>x</math> and <math>y</math> for <math> m  &gt; 1</math>). The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.</p>                                                                                                                                                                                                                                                                               |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Naïve Algorithm 2/2. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Downsides / - Does not work for $x = x / 0$ 1 / - Does not work for $ m  > 1$ , since gaps arise / (solution: swap the roles of $x$ and $y$ for $ m  > 1$ ). The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself       | Can you turn 'Naïve Algorithm 2/2' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                        |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Page 10                     | Digital Difference Analyzer (DDA) 1/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source cue                  | - Reuse the last computed $y$ to avoid multiplications in the loop / $x \rightarrow x + 1 \Rightarrow (x, y) \rightarrow (x + 1, y + m)$ / void drawLine(int x0, int y0, int x1, int y1) { / float m = float(y1 - y0) / float(x1 - x0); // Calculate the slope / float y = y0; // Start y at y0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Professor-style explanation | The slide 'Digital Difference Analyzer (DDA) 1/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Reuse the last computed $y$ to avoid multiplications in the loop / $x \rightarrow x + 1 \Rightarrow (x, y) \rightarrow (x + 1, y + m)$ / void drawLine(int x0, int y0, int x1, int y1) { / float m = float(y1 - y0) / float(x1 - x0); // Calculate the slope / float y = y0; // Start y at y0. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | The slide 'Digital Difference Analyzer (DDA) 2/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Algorithm can be extended to relax endpoint order / void drawLine(int x0, int y0, int x1, int y1) { / int sx = (x0 < x1 ? 1 : -1); // Determine x direction / float sm = sx * float(y1 - y0) / float(x1 - x0); // Calculate slope multiplied by step / float y = y0; // Start y at y0. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Digital Difference Analyzer (DDA) 2/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Algorithm can be extended to relax endpoint order / void drawLine(int x0, int y0, int x1, int y1) { / int sx = (x0 < x1 ? 1 : -1); // Determine x direction / float sm = sx * float(y1 - y0) / float(x1 - x0); // Calculate slope multiplied by step / float y = y0; // Start y at y0. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself              | Can you turn 'Digital Difference Analyzer (DDA) 2/3' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Source cue                  | - Downsides / - Does not work for $x = x / 0$ 1 / - Does not work for $ m  > 1$ , since gaps arise / (solution: swap the roles of x and y for $ m  > 1$ )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Professor-style explanation | The slide 'Digital Difference Analyzer (DDA) 3/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Downsides / - Does not work for $x = x / 0$ 1 / - Does not work for $ m  > 1$ , since gaps arise / (solution: swap the roles of x and y for $ m  > 1$ ). The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Digital Difference Analyzer (DDA) 3/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Downsides / - Does not work for $x = x / 0$ 1 / - Does not work for $ m  > 1$ , since gaps arise / (solution: swap the roles of x and y for $ m  > 1$ ). The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you turn 'Digital Difference Analyzer (DDA) 3/3' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Page 13                     | Midpoint-Line Algorithm 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | - Assumption 1: $0 \leq m \leq 1$ / (without loss of generality, as otherwise mirroring on axes/diagonals) / - Lower left end point $P = (x, y)$ , / 0 0 0 / upper right end point $P = (x, y)$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Professor-style explanation | The slide 'Midpoint-Line Algorithm 1/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Assumption 1: $0 \leq m \leq 1$ / (without loss of generality, as otherwise mirroring on axes/diagonals) / - Lower left end point $P = (x, y)$ , / 0 0 0 / upper right end point $P = (x, y)$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Midpoint-Line Algorithm 1/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Assumption 1: $0 \leq m \leq 1$ / (without loss of generality, as otherwise mirroring on axes/diagonals) / - Lower left end point $P = (x, y)$ , / 0 0 0 / upper right end point $P = (x, y)$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you explain which samples/fragments are generated by 'Midpoint-Line Algorithm 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 14                     | Midpoint-Line Algorithm 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | <p>The slide 'Midpoint-Line Algorithm 2/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Observation / - E is closer to the line if M is above the line / - NE is closer to the line if M is below the line / - Vertical distance between pixel to chose / and the actual line segment is always <math>&lt; 0.5</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p>                                                                                  |
| Technical commentary        | <p>This slide is about Midpoint-Line Algorithm 2/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Observation / - E is closer to the line if M is above the line / - NE is closer to the line if M is below the line / - Vertical distance between pixel to chose / and the actual line segment is always <math>&lt; 0.5</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Implicit Function' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Line equation usually given as explicit function <math>f(x) / f x = y = m \cdot x + B = \cdot x + B</math>, with <math>dx = x - x</math> and <math>dy = y - y / 1 \text{ o } 1 \text{ o}</math> / - Line equation can also be written as implicit function <math>F(x, y) / F x, y = a \cdot x + b \cdot y + c = 0</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Technical commentary | This slide is about Implicit Function. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Line equation usually given as explicit function $f(x) / f x = y = m \cdot x + B = \cdot x + B$ , with $dx = x - x$ and $dy = y - y / 1 o 1 o /$ - Line equation can also be written as implicit function $F(x, y) / F x, y = a \cdot x + b \cdot y + c = 0$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself       | Can you explain which samples/fragments are generated by 'Implicit Function'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Decision Variable d' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Sign of $F(M)$ is sufficient to decide which point is chosen / - Define decision variable $d$ as $d = F M = F(x + 1, y + ) / p p /$ - If $d > 0$ , select NE (M below the line) / - If $d < 0$ , select E (M above the line). The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Decision Variable d. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Sign of $F(M)$ is sufficient to decide which point is chosen / - Define decision variable $d$ as $d = F M = F(x + 1, y + ) / p p /$ - If $d > 0$ , select NE (M below the line) / - If $d < 0$ , select E (M above the line). The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you turn 'Decision Variable d' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Page 17                     | Update of d for E                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Source cue                  | - Previous decision variable was given by / 1 1 / $d = F x + 1, y + = a \cdot x + 1 + b \cdot y + + c /$ old $p p p p / 2 2$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Update of d for E' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Previous decision variable was given by / $1 \ 1 / d = F \ x + 1, y + = a \cdot x + 1 + b \cdot y + + c / \text{old } p \ p \ p / 2 \ 2$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Update of d for E. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Previous decision variable was given by / $1 \ 1 / d = F \ x + 1, y + = a \cdot x + 1 + b \cdot y + + c / \text{old } p \ p \ p / 2 \ 2$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself              | Can you turn 'Update of d for E' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

The terms form an input-operation-output relation: - Previous decision variable was given by / $1 \ 1 / d = F \ x + 1, y + = a \cdot x + 1 + b \cdot y + + c / \text{old } p \ p \ p / 2 \ 2$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you turn 'Update of d for NE' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Source cue                  | - In each step, the algorithm selects between two pixels NE and E / based on sign of decision variable d / - Depending on the choice, decision variable is updated / by adding difference $\Delta NE$ or $\Delta E$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | The slide 'Proceeding' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - In each step, the algorithm selects between two pixels NE and E / based on sign of decision variable d / - Depending on the choice, decision variable is updated / by adding difference $\Delta NE$ or $\Delta E$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |

| Professor-style explanation | The slide 'Initializing d' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - First midpoint M is located at $(x + 1, y + ) / 0 0 / 1 1 b / F x + 1, y + = a \cdot x + 1 + b \cdot y + + c = a \cdot x + b \cdot y + c + a + / 0 0 0 0 0 0$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                 |
| Technical commentary        | This slide is about Initializing d. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - First midpoint M is located at $(x + 1, y + ) / 0 0 / 1 1 b / F x + 1, y + = a \cdot x + 1 + b \cdot y + + c = a \cdot x + b \cdot y + c + a + / 0 0 0 0 0 0$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you turn 'Initializing d' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Page 21                     | Using d                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Source cue                  | - Midpoint line algorithms uses d as follows / $d = 2 \cdot dy - dx$ / start / $\Delta E = 2 \cdot dy - dx$ / $\Delta E = 2 \cdot dy$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Professor-style explanation | The slide 'Using d' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Midpoint line algorithms uses d as follows / $d = 2 \cdot dy - dx$ / start / $\Delta E = 2 \cdot dy - dx$ / $\Delta E = 2 \cdot dy$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Using d. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Midpoint line algorithms uses d as follows / $d = 2 \cdot dy - dx$ / start / $\Delta E = 2 \cdot dy - dx$ / $\Delta E = 2 \cdot dy$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you explain which samples/fragments are generated by 'Using d'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Page 22                     | Pseudo Code - Simple Version                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Source cue                  | void midPointLine(int x0, int y0, int x1, int y1) { / int dx = x1 - x0; // Calculate delta x / int dy = y1 - y0; // Calculate delta y / int d = 2 * dy - dx; // Initial decision variable / int dE = 2 * dy; // Increment used for move to E                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | The slide 'Pseudo Code - Simple Version' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: <code>void midPointLine(int x0, int y0, int x1, int y1) { / int dx = x1 - x0; // Calculate delta x / int dy = y1 - y0; // Calculate delta y / int d = 2 * dy - dx; // Initial decision variable / int dE = 2 * dy; // Increment used for move to E. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.</code> |
| Technical commentary        | This slide is about Pseudo Code - Simple Version. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: <code>void midPointLine(int x0, int y0, int x1, int y1) { / int dx = x1 - x0; // Calculate delta x / int dy = y1 - y0; // Calculate delta y / int d = 2 * dy - dx; // Initial decision variable / int dE = 2 * dy; // Increment used for move to E. The slide groups them because one object or quantity is processed into another result used later in rendering.</code>                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you turn 'Pseudo Code - Simple Version' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | The slide 'Example' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Draw line from (5, 8) to (9, 11) / - Order of values for d / - 2, 0, 6, 4 / - Order of chosen pixels / - NE, E, NE, NE. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Example. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Draw line from (5, 8) to (9, 11) / - Order of values for d / - 2, 0, 6, 4 / - Order of chosen pixels / - NE, E, NE, NE. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you explain which samples/fragments are generated by 'Example'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 24                     | Evaluation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Source cue                  | - Necessary arithmetic operations / - As only integer values are used, only integer operations are necessary / - Additions/subtractions only and multiplication by 2 / (left shift by 1 bit position) / - No multiplications in the loop                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Evaluation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Necessary arithmetic operations / - As only integer values are used, only integer operations are necessary / - Additions/subtractions only and multiplication by 2 / (left shift by 1 bit position) / - No multiplications in the loop. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Evaluation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Necessary arithmetic operations / - As only integer values are used, only integer operations are necessary / - Additions/subtractions only and multiplication by 2 / (left shift by 1 bit position) / - No multiplications in the loop. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you turn 'Evaluation' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Page 25                     | Pseudo Code - Reversible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Source cue                  | void drawLine(int x0, int y0, int x1, int y1) { / int dx = abs(x1 - x0); // Calculate absolute delta x / int sx = (x0 < x1 ? 1 : -1); // Set step x based on direction / int dy = abs(y1 - y0); // Calculate absolute delta y / int sy = (y0 < y1 ? 1 : -1); // Set step y based on direction                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | The slide 'Pseudo Code - Reversible' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: <code>void drawLine(int x0, int y0, int x1, int y1) { / int dx = abs(x1 - x0); // Calculate absolute delta x / int sx = (x0 &lt; x1 ? 1 : -1); // Set step x based on direction / int dy = abs(y1 - y0); // Calculate absolute delta y / int sy = (y0 &lt; y1 ? 1 : -1); // Set step y based on direction. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.</code> |
| Technical commentary        | This slide is about Pseudo Code - Reversible. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: <code>void drawLine(int x0, int y0, int x1, int y1) { / int dx = abs(x1 - x0); // Calculate absolute delta x / int sx = (x0 &lt; x1 ? 1 : -1); // Set step x based on direction / int dy = abs(y1 - y0); // Calculate absolute delta y / int sy = (y0 &lt; y1 ? 1 : -1); // Set step y based on direction. The slide groups them because one object or quantity is processed into another result used later in rendering.</code>                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you turn 'Pseudo Code - Reversible' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Page 26                     | 6.2 Triangle Edge Rasterization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Source cue                  | Drawing a one pixel thick triangle edge                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Professor-style explanation | The slide '6.2 Triangle Edge Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: Drawing a one pixel thick triangle edge. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.        |
| Technical commentary        | This slide is about 6.2 Triangle Edge Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: Drawing a one pixel thick triangle edge. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you explain which samples/fragments are generated by '6.2 Triangle Edge Rasterization'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | The slide 'Triangle Edges 1/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Using midpoint line algorithm for triangle edge rasterization / - Provides pixels closest to triangle edge / - Does not consider if pixel lies inside or outside triangle / $\Rightarrow$ Edge pixels can penetrate into interior of adjacent triangles. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Triangle Edges 1/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Using midpoint line algorithm for triangle edge rasterization / - Provides pixels closest to triangle edge / - Does not consider if pixel lies inside or outside triangle / $\Rightarrow$ Edge pixels can penetrate into interior of adjacent triangles. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you explain which samples/fragments are generated by 'Triangle Edges 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | <p>The slide 'Triangle Edges 2/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Midpoint line algorithm must consider inside vs. outside pixels</li> <li>- Adaptation of the midpoint line algorithm</li> <li>- Restriction to pixels strictly inside triangle</li> <li>- Must be applied to line rasterization also for consistency reasons</li> <li>- Definition of triangle inside. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</li> </ul> |
| Technical commentary        | <p>This slide is about Triangle Edges 2/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Midpoint line algorithm must consider inside vs. outside pixels</li> <li>- Adaptation of the midpoint line algorithm</li> <li>- Restriction to pixels strictly inside triangle</li> <li>- Must be applied to line rasterization also for consistency reasons</li> <li>- Definition of triangle inside. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you explain which samples/fragments are generated by 'Triangle Edges 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | <p>The slide 'Edge Rasterization 1/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Triangle edge rasterization can exploit edge coherence</li> <li>- Two edges of triangle intersect a scanline</li> <li>- Same edges intersected by scanline <math>i</math> likely also intersect scanline <math>i + 1</math></li> <li>- Due to coherence, intersections can be calculated incrementally</li> <li>- For each increase of <math>y \rightarrow y + 1</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</li> </ul> |
| Technical commentary        | <p>This slide is about Edge Rasterization 1/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Triangle edge rasterization can exploit edge coherence</li> <li>- Two edges of triangle intersect a scanline</li> <li>- Same edges intersected by scanline <math>i</math> likely also intersect scanline <math>i + 1</math></li> <li>- Due to coherence, intersections can be calculated incrementally</li> <li>- For each increase of <math>y \rightarrow y + 1</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | <p>The slide 'Edge Rasterization 2/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Integer arithmetic can be used for (left) edges with slopes <math>&gt; 1</math> / - Consider <math>dx dy = (x_{max} - x_{min}) / (y_{max} - y_{min})</math> / - <math>x</math> is only changed by <math>dx dy</math> / <math>\Rightarrow x</math> can be represented as a fraction with denominator <math>(y_{max} - y_{min})</math> / - Let <math>a</math> be the integer part. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Edge Rasterization 2/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Integer arithmetic can be used for (left) edges with slopes <math>&gt; 1</math> / - Consider <math>dx dy = (x_{max} - x_{min}) / (y_{max} - y_{min})</math> / - <math>x</math> is only changed by <math>dx dy</math> / <math>\Rightarrow x</math> can be represented as a fraction with denominator <math>(y_{max} - y_{min})</math> / - Let <math>a</math> be the integer part. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | <p>Can you explain which samples/fragments are generated by 'Edge Rasterization 2/3'?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide 'Edge Rasterization 3/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: <code>void leftEdgeScan(int x0, int y0, int x1, int y1) { // slope &gt; 1 / int d = y1 - y0; // denominator (Nenner) / int n = x1 - x0; // numerator (Zähler) / int a = x0; // integer part of x / int b = d; // fraction part of x plus d</code>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Edge Rasterization 3/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: <code>void leftEdgeScan(int x0, int y0, int x1, int y1) { // slope &gt; 1 / int d = y1 - y0; // denominator (Nenner) / int n = x1 - x0; // numerator (Zähler) / int a = x0; // integer part of x / int b = d; // fraction part of x plus d</code>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide '6.3 Region Filling' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: Homogeneous coloring of regions. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |

|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about 6.3 Region Filling. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: Homogeneous coloring of regions. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                             |
| Check yourself       | Can you explain which samples/fragments are generated by '6.3 Region Filling'?                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | The slide 'Region Types 1/2' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - 4-connected / - All pixels of region can be reached by following movements / - Left, right, bottom, top / - 8-connected / - All pixels of region can be reached by following movements. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Region Types 1/2. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - 4-connected / - All pixels of region can be reached by following movements / - Left, right, bottom, top / - 8-connected / - All pixels of region can be reached by following movements. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you turn 'Region Types 1/2' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Source cue                  | - Color-based / - Starting at pixel P, determine largest contiguous region / which pixels have a specific color / - Color assignment done by flood fill algorithms / - Border-based                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Professor-style explanation | The slide 'Region Spezifikation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Color-based / - Starting at pixel P, determine largest contiguous region / which pixels have a specific color / - Color assignment done by flood fill algorithms / - Border-based. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Region Spezifikation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Color-based / - Starting at pixel P, determine largest contiguous region / which pixels have a specific color / - Color assignment done by flood fill algorithms / - Border-based. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | <p>The slide 'Flood Fill Algorithm' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: void floodFill4(int x, int y, Color oldC, Color newC) { / if ((x &lt; 0)    (x &gt;= width)) return; // Return if x is out of bounds / if ((y &lt; 0)    (y &gt;= height)) return; // Return if y is out of bounds / if (oldC == readPixel(x, y)) { // Check if the current color matches oldC / writePixel(x, y, newC); // Change the color of the pixel. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.</p> |
| Technical commentary        | <p>This slide is about Flood Fill Algorithm. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: void floodFill4(int x, int y, Color oldC, Color newC) { / if ((x &lt; 0)    (x &gt;= width)) return; // Return if x is out of bounds / if ((y &lt; 0)    (y &gt;= height)) return; // Return if y is out of bounds / if (oldC == readPixel(x, y)) { // Check if the current color matches oldC / writePixel(x, y, newC); // Change the color of the pixel. The slide groups them because one object or quantity is processed into another result used later in rendering.</p>                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Even a sparse slide usually names a relation you must be able to explain in words.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | <p>Can you turn 'Flood Fill Algorithm' into a causal sentence instead of repeating the slide title?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Page 37                     | Boundary Fill Algorithm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Boundary Fill Algorithm' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: <code>void boundaryFill4(int x, int y, Color oldC, Color newC) { / if ((x &lt; 0)    (x &gt;= width)) return; // Return if x is out of bounds / if ((y &lt; 0)    (y &gt;= height)) return; // Return if y is out of bounds / Color c = readPixel(x, y); / if (c == oldC) return; // Return if pixel is a boundary pixel. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.</code> |
| Technical commentary        | This slide is about Boundary Fill Algorithm. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: <code>void boundaryFill4(int x, int y, Color oldC, Color newC) { / if ((x &lt; 0)    (x &gt;= width)) return; // Return if x is out of bounds / if ((y &lt; 0)    (y &gt;= height)) return; // Return if y is out of bounds / Color c = readPixel(x, y); / if (c == oldC) return; // Return if pixel is a boundary pixel. The slide groups them because one object or quantity is processed into another result used later in rendering.</code>                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you turn 'Boundary Fill Algorithm' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Page 38                     | Fill Algorithms                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Source cue                  | - High number of recursions can lead to stack overflow / - Use smarter data structures, i.e., queues and stacks / Queue Stack                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Professor-style explanation | The slide 'Fill Algorithms' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - High number of recursions can lead to stack overflow / - Use smarter data structures, i.e., queues and stacks / Queue Stack. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                                                                           |
| Technical commentary        | This slide is about Fill Algorithms. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - High number of recursions can lead to stack overflow / - Use smarter data structures, i.e., queues and stacks / Queue Stack. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you turn 'Fill Algorithms' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Page 39                     | 6.4 Scanline-Based Triangle Rasterization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Source cue                  | Segment-based rasterization of the simplest type of polygon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Professor-style explanation | <p>The slide '6.4 Scanline-Based Triangle Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: Segment-based rasterization of the simplest type of polygon. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about 6.4 Scanline-Based Triangle Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: Segment-based rasterization of the simplest type of polygon. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | <p>The slide 'Triangle Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Triangle rasterization</li> <li>- Rasterize filled triangles is main task in real-time rendering</li> <li>- Realization through graphics hardware desired</li> <li>- General polygons split into triangles through tessellation</li> <li>- Rasterization requires three steps. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</li> </ul> |
| Technical commentary        | <p>This slide is about Triangle Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Triangle rasterization</li> <li>- Rasterize filled triangles is main task in real-time rendering</li> <li>- Realization through graphics hardware desired</li> <li>- General polygons split into triangles through tessellation</li> <li>- Rasterization requires three steps. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Check yourself              | Can you explain which samples/fragments are generated by 'Triangle Rasterization'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | <p>The slide 'Scanline-Based Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Rasterization through scanline conversion exploits spatial coherence</li> <li>/ - Pixels of a scanline are colored similarly</li> <li>/ - Adjacent scanlines span similar pixels</li> <li>/ - Adjacent scanlines are colored similarly</li> <li>/ - Scanline segments can be calculated.</li> </ul> <p>A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Scanline-Based Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation:</p> <ul style="list-style-type: none"> <li>- Rasterization through scanline conversion exploits spatial coherence</li> <li>/ - Pixels of a scanline are colored similarly</li> <li>/ - Adjacent scanlines span similar pixels</li> <li>/ - Adjacent scanlines are colored similarly</li> <li>/ - Scanline segments can be calculated.</li> </ul> <p>A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you explain which samples/fragments are generated by 'Scanline-Based Rasterization'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Page 42                     | Algorithm Overview                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | The slide 'Algorithm Overview' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Observation: triangle can be split into top and bottom half / - For each half two edge pixels and one segment exist / - Segments differ only slightly, depending on edge slope / - Procedure / - Sort triangle vertices based on y-coordinate. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Algorithm Overview. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Observation: triangle can be split into top and bottom half / - For each half two edge pixels and one segment exist / - Segments differ only slightly, depending on edge slope / - Procedure / - Sort triangle vertices based on y-coordinate. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you state the coordinate space before and after 'Algorithm Overview'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Slope Calculation' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Calculate slope for each triangle edge: $1/A = dx/dy$ / - $\Delta = (x - x_0)/(y - y_0)$ / $02\ 2\ 0\ 2\ 0$ / - $\Delta = (x - x_1)/(y - y_1)$ / $01\ 1\ 0\ 1\ 0$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Technical commentary | This slide is about Slope Calculation. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Calculate slope for each triangle edge: $1/A = dx/dy$ / $- \Delta = (x - x_0)/(y - y_0)$ / $02 \ 2 \ 0 \ 2 \ 0$ / $- \Delta = (x - x_0)/(y - y_0)$ / $01 \ 1 \ 0 \ 1 \ 0$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself       | Can you explain which samples/fragments are generated by 'Slope Calculation'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Source cue                  | void processTriangle(int x0, int y0, float delta02, float delta01, int Nbottom, int Ntop) { / float XLeft = x0; // Start position for left x / float XRight = x0; // Start position for right x / int Y = y0; // Start position for y / float DeltaLeft = delta02; // Delta for left x for bottom half                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Professor-style explanation | The slide 'Pseudo Code' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: void processTriangle(int x0, int y0, float delta02, float delta01, int Nbottom, int Ntop) { / float XLeft = x0; // Start position for left x / float XRight = x0; // Start position for right x / int Y = y0; // Start position for y / float DeltaLeft = delta02; // Delta for left x for bottom half. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Pseudo Code. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: void processTriangle(int x0, int y0, float delta02, float delta01, int Nbottom, int Ntop) { / float XLeft = x0; // Start position for left x / float XRight = x0; // Start position for right x / int Y = y0; // Start position for y / float DeltaLeft = delta02; // Delta for left x for bottom half. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you explain which samples/fragments are generated by 'Pseudo Code'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Source cue                  | - Each segment generates fragments / - Rendering pipeline processes generated fragments / (x , y ) / (e.g., depth testing, alpha blending) right s / (x , y )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Professor-style explanation | <p>The slide 'Segment Rasterization' explains rendering as a chain of object transformations. At the beginning there is scene information: models, vertices, primitives, attributes, camera state, and rendering state. The geometry part of the pipeline changes where the objects are and how they are represented; vertices become positioned data, vertices are assembled into primitives, and primitives are prepared for conversion to the image grid. The terms are successive representations in object-based rendering:</p> <p>- Each segment generates fragments / - Rendering pipeline processes generated fragments / (x , y ) / (e.g., depth testing, alpha blending) right s / (x , y ). Scene data becomes vertices, vertices become primitives, primitives become fragments, and only passing fragments update pixels. The important story is that the same scene information changes form several times. A triangle is first model data, then transformed geometry, then a projected primitive, then a set of fragments, and finally only some of those fragments become pixel updates. This is why the pipeline is not just a drawing diagram; it is the explanation for where image errors can enter.</p> |
| Technical commentary        | <p>This slide is about Segment Rasterization. Scene or model data moves through a sequence of representations: vertices, primitives, fragments, tests, and framebuffer updates. Each named object is one stage in that conversion. The terms are successive representations in object-based rendering:</p> <p>- Each segment generates fragments / - Rendering pipeline processes generated fragments / (x , y ) / (e.g., depth testing, alpha blending) right s / (x , y ). Scene data becomes vertices, vertices become primitives, primitives become fragments, and only passing fragments update pixels.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Why it matters              | Pipeline understanding lets you localize rendering errors instead of guessing randomly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you name the input and output representation for 'Segment Rasterization' in the rendering pipeline?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Page 46                     | Vertex Attribute Interpolation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Source cue                  | - During rasterization vertex attributes (e.g., color, depth) / must be interpolated over triangle / (x , y , z ) / right s right / - Bilinear interpolation can be used                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Vertex Attribute Interpolation' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - During rasterization vertex attributes (e.g., color, depth) / must be interpolated over triangle / $(x, y, z)$ / right s right / - Bilinear interpolation can be used. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Vertex Attribute Interpolation. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - During rasterization vertex attributes (e.g., color, depth) / must be interpolated over triangle / $(x, y, z)$ / right s right / - Bilinear interpolation can be used. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you explain which samples/fragments are generated by 'Vertex Attribute Interpolation'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Incremental Interpolation 1/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Spatial coherence allows for an incremental attribute interpolation / - Example: consider triangle's plane equation for calculating z increments / - $Ax + By + Cz + D = 0$ / - With plane coefficients A, B, C: $A, B, C = V - V \times (V - V) / 2 \ 0 \ 1 \ 2$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Technical commentary | This slide is about Incremental Interpolation 1/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Spatial coherence allows for an incremental attribute interpolation / - Example: consider triangle's plane equation for calculating z increments / - $Ax + By + Cz + D = 0$ / - With plane coefficients A, B, C: $A, B, C = V - V \times (V - V) / 2 \ 0 \ 1 \ 2$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself       | Can you explain which samples/fragments are generated by 'Incremental Interpolation 1/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | The slide 'Incremental Interpolation 2/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Increments dzdx and dzdy are used to incrementally modify given z value, / i.e., when moving from (x, y) to (x + 1, y) or (x, y + 1) / - Case 1: next fragment in scanline (horizontal change by +1) / - $x \rightarrow x \Rightarrow z \blacksquare z + dzdx / i \ i+1 \ i$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Incremental Interpolation 2/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Increments dzdx and dzdy are used to incrementally modify given z value, / i.e., when moving from (x, y) to (x + 1, y) or (x, y + 1) / - Case 1: next fragment in scanline (horizontal change by +1) / - $x \rightarrow x \Rightarrow z \blacksquare z + dzdx / i \ i+1 \ i$ . A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you explain which samples/fragments are generated by 'Incremental Interpolation 2/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Page 49                     | Incremental Interpolation 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Source cue                  | - All vertex attributes can be interpolated incrementally analogous to depth / - Colors (r, g, b, a) / - Texture coordinates (u, v) / - ... / - For each attribute $\theta$ define                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Professor-style explanation | The slide 'Incremental Interpolation 3/3' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - All vertex attributes can be interpolated incrementally analogous to depth / - Colors (r, g, b, a) / - Texture coordinates (u, v) / - ... / - For each attribute $\theta$ define. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Incremental Interpolation 3/3. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - All vertex attributes can be interpolated incrementally analogous to depth / - Colors (r, g, b, a) / - Texture coordinates (u, v) / - ... / - For each attribute $\theta$ define. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you state the coordinate space before and after 'Incremental Interpolation 3/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | The slide '6.5 Tile-Based Triangle Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: Parallel tile-based triangle rasterization. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.                                                                                                                                                                      |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Technical commentary | This slide is about 6.5 Tile-Based Triangle Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: Parallel tile-based triangle rasterization. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                           |

| Page 51                     | Tile-Based Triangle Rasterization                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Source cue                  | - Modern GPUs have a block-wise structure, / where one processor is responsible for one screen tile of adjacent pixels / - Segment-based triangled rasterization is difficult to parallelize / - Tile-based rasterization is a better fit with modern GPUs / - Advantage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Professor-style explanation | The slide 'Tile-Based Triangle Rasterization' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Modern GPUs have a block-wise structure, / where one processor is responsible for one screen tile of adjacent pixels / - Segment-based triangled rasterization is difficult to parallelize / - Tile-based rasterization is a better fit with modern GPUs / - Advantage. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Tile-Based Triangle Rasterization. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Modern GPUs have a block-wise structure, / where one processor is responsible for one screen tile of adjacent pixels / - Segment-based triangled rasterization is difficult to parallelize / - Tile-based rasterization is a better fit with modern GPUs / - Advantage. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you explain which samples/fragments are generated by 'Tile-Based Triangle Rasterization'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Page 52                     | Edge-Based Triangle Representation 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Source cue                  | - Edge-based area representation is possible through implicit edge functions / - Implicit edge function can be defined based on two edge vertices / $V = (x, y)$ and $V = (x, y) / 0 \ 0 \ 0 \ 1 \ 1 \ 1$ / - For a given coordinate $(x, y)$ , the implicit edge function is defined as                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Professor-style explanation | The slide 'Edge-Based Triangle Representation 1/2' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Edge-based area representation is possible through implicit edge functions / - Implicit edge function can be defined based on two edge vertices / $V = (x, y)$ and $V = (x, y) / 0 \ 0 \ 0 \ 1 \ 1 \ 1$ / - For a given coordinate $(x, y)$ , the implicit edge function is defined as. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Edge-Based Triangle Representation 1/2. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Edge-based area representation is possible through implicit edge functions / - Implicit edge function can be defined based on two edge vertices / $V = (x, y)$ and $V = (x, y) / 0 \ 0 \ 0 \ 1 \ 1 \ 1$ / - For a given coordinate $(x, y)$ , the implicit edge function is defined as. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you state the coordinate space before and after 'Edge-Based Triangle Representation 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Edge-Based Triangle Representation 2/2' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - To represent a triangle, three implicit edge functions are combined / - <math>E_x, y = y - y \cdot x - x - x \cdot y + B \cdot x - x / 01\ 1\ 0\ 1\ 0\ 01\ 1\ 0</math> / - <math>E_x, y = y - y \cdot x - x - x \cdot y + B \cdot x - x / 12\ 2\ 1\ 2\ 1\ 12\ 2\ 1</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Edge-Based Triangle Representation 2/2. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - To represent a triangle, three implicit edge functions are combined / - <math>E_x, y = y - y \cdot x - x - x \cdot y + B \cdot x - x / 01\ 1\ 0\ 1\ 0\ 01\ 1\ 0</math> / - <math>E_x, y = y - y \cdot x - x - x \cdot y + B \cdot x - x / 12\ 2\ 1\ 2\ 1\ 12\ 2\ 1</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide 'Rasterization Procedure' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: 1. Determine tiles which are (partially) covering triangle / (e.g., easiest approximation would be bounding box) / 2. For each covering tile / - For each pixel / - If all implicit edge functions evaluate to <math>&lt; 0</math> 2. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |

| Technical commentary | This slide is about Rasterization Procedure. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: 1. Determine tiles which are (partially) covering triangle / (e.g., easiest approximation would be bounding box) / 2. For each covering tile / - For each pixel / - If all implicit edge functions evaluate to $< 0$ 2. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself       | Can you explain which samples/fragments are generated by 'Rasterization Procedure'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide 'between adjacent triangles' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Pixel-based displays require the rasterization of primitives / - Rasterization fidelity is critical for image quality / - Rasterization is time-critical and should be optimized for hardware / - Focus on triangles due to speed and ease of tessellation of other polygons / - Segment-based triangle rasterization avoids overlap. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about between adjacent triangles. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Pixel-based displays require the rasterization of primitives / - Rasterization fidelity is critical for image quality / - Rasterization is time-critical and should be optimized for hardware / - Focus on triangles due to speed and ease of tessellation of other polygons / - Segment-based triangle rasterization avoids overlap. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Check yourself              | Can you explain which samples/fragments are generated by 'between adjacent triangles'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Page 56                     | Literature and other sources used in this chapter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Literature and other sources used in this chapter' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail.                                                                                                                                                                                 |
| Technical commentary        | This slide is about Literature and other sources used in this chapter. The slide lists source material or chapter references that support the technical content and give names for further reading. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Why it matters              | Reference slides provide the source trail for definitions, algorithms, and deeper explanations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you identify which source or topic 'Literature and other sources used in this chapter' points to for deeper study?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | The slide 'Practice, Addison-Wesley.' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Text Books / - Foley J., van Dam, A., Feiner, S. (2013). Computer Graphics: Principles and / Practice, Addison-Wesley. / - Research Publications / - Bresenham, J. E. (1998). Algorithm for computer control of a digital plotter. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Technical commentary | This slide is about Practice, Addison-Wesley.. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Text Books / - Foley J., van Dam, A., Feiner, S. (2013). Computer Graphics: Principles and / Practice, Addison-Wesley. / - Research Publications / - Bresenham, J. E. (1998). Algorithm for computer control of a digital plotter. The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself       | Can you turn 'Practice, Addison-Wesley.' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | The slide 'Slide for Future: Sustainability in CG (@ EG25)' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: also @ IEEE VR. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |

The terms form an input-operation-output relation: Unoptimized Optimized Unoptimized Optimized / Inverse Simulation of Radiative Thermal Transport / Christian Freude, Lukas Lipp, Matthias Zezulka, Florian Rist, Michael Wimmer, David Hahn. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you turn 'Slide for Future: Sustainability in CG (@ EG25)' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | The slide 'Slide for Future: Sustainability in CG (@ EG25)' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: Optimizing Free-Form Grid Shells with Reclaimed Elements under Inventory Constraints / Andrea Favilli, Francesco Laccone, Paolo Cignoni, Luigi Malomo, Daniela Giorgi. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                      |
| Technical commentary        | This slide is about Slide for Future: Sustainability in CG (@ EG25). The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: Optimizing Free-Form Grid Shells with Reclaimed Elements under Inventory Constraints / Andrea Favilli, Francesco Laccone, Paolo Cignoni, Luigi Malomo, Daniela Giorgi. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                 |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you turn 'Slide for Future: Sustainability in CG (@ EG25)' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 61                     | Slide for Future: Sustainability in CG (@ EG25)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | Stress-Aligned Hexahedral Lattice Structures / Dennis Bukenberger, Junpeng Wang, Jun Wu, Rüdiger Westermann                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | The slide 'Slide for Future: Sustainability in CG (@ EG25)' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: Stress-Aligned Hexahedral Lattice Structures / Dennis Bukenberger, Junpeng Wang, Jun Wu, Rüdiger Westermann. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Slide for Future: Sustainability in CG (@ EG25). The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: Stress-Aligned Hexahedral Lattice Structures / Dennis Bukenberger, Junpeng Wang, Jun Wu, Rüdiger Westermann. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you turn 'Slide for Future: Sustainability in CG (@ EG25)' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 06.1 Line Rasterization

Source location: Section 6.1

### Commentary

A mathematical line has infinitely many points, but a raster display has a finite grid. Line rasterization decides which grid cells or samples best approximate the ideal line. The algorithm must balance accuracy, speed, and consistency.

Incremental algorithms avoid recomputing expensive formulas for every pixel. The important idea is to step along one axis and update an error term that decides when to step along the other axis.

### Mental model

Rasterizing a line means approximating a continuous path by grid decisions.

### Check yourself

Why are incremental error updates useful in line rasterization?

## 06.2 Triangle Edge Rasterization

Source location: Section 6.2

### Commentary

Triangles are the core primitive in real-time rendering. Edge functions or half-space tests decide whether a sample lies inside the triangle. This allows the rasterizer to test coverage systematically.

Coverage is not final visibility. A covered sample becomes a fragment candidate. Depth testing, stencil testing, blending, and other operations still decide whether the framebuffer changes.

### Mental model

Triangle rasterization answers the question: which samples are inside this projected triangle?

### Check yourself

What later stage can reject a fragment after triangle coverage succeeds?

## 06.3 Region Filling

Source location: Section 6.3

### Commentary

Region filling generalizes the idea of determining interior samples. The algorithm must identify connected areas or spans that should receive color. This connects rasterization to scan conversion and image-space reasoning.

The practical issue is avoiding gaps, double fills, or inconsistent boundary handling. Small choices at edges can become visible artifacts when many primitives meet.

### Mental model

Filling is about turning boundary descriptions into consistent interior samples.

### Check yourself

Why can inconsistent edge rules create cracks between adjacent primitives?

## 06.4 Scanline-Based Triangle Rasterization

Source location: Section 6.4

### Commentary

Scanline rasterization processes horizontal rows of the image. For each row that crosses a triangle, the algorithm finds the covered interval and fills the span. Attribute interpolation can be updated along edges and across each span.

The method is intuitive because it follows the memory layout of many images. It also demonstrates why interpolation is tied to rasterization: once you know a sample location inside the primitive, you can interpolate depth, color, normals, or texture coordinates.

## Mental model

Each scanline asks: where does this triangle enter and leave this row?

## Check yourself

Which attributes might be interpolated while filling triangle spans?

# 06.5 Tile-Based Triangle Rasterization

Source location: Section 6.5

## Commentary

Tile- or block-based approaches group pixels into small regions. This can improve locality and parallel work distribution. Modern GPUs often reason in blocks or tiles internally because rendering is massively parallel.

For the exam, connect this to efficiency. The mathematical goal is still coverage, but the implementation is organized to use hardware resources well.

## Mental model

Block-based rasterization keeps the same coverage problem but changes the work organization.

## Check yourself

Why is block organization attractive for parallel graphics hardware?

# End-of-lecture summary

If you remember only one thing from Lecture 06, remember this: This lecture explains how continuous primitives become discrete fragments on a grid. Rasterization is the bridge from geometric descriptions to sample-based image generation.

Before moving on, you should be able to explain the lecture without reading slide bullets aloud. Use the vocabulary from the slides, but add causal links: why a step exists, what data it consumes, what it produces, and what can go wrong.

# Lecture 07 - Visibility Determination

This lecture asks which surfaces are visible from a viewpoint. Rasterization can generate many fragment candidates, but visibility decides which ones should affect the image.

## How to read this lecture

- Read the section commentary before looking at the raw slide bullets.
- Use the mental model as the short version you should remember.
- Answer the check question without notes before continuing.

## Per-slide commentary

Each extracted slide page gets its own note. Use this section as the spoken commentary that the terse slide deck is missing.

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Source cue                  | No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Professor-style explanation | The slide 'Visual or title slide' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail. |
| Technical commentary        | This slide is about Visual or title slide. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                              |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you turn 'Visual or title slide' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | The slide 'Visibility Determination' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Problem / - Given scene objects and virtual camera / - Determine visible parts of scene objects / - Not occluded by same scene object / - Not occluded by other scene objects. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.                                                                                                                      |
| Technical commentary        | This slide is about Visibility Determination. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Problem / - Given scene objects and virtual camera / - Determine visible parts of scene objects / - Not occluded by same scene object / - Not occluded by other scene objects. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you decide whether 'Visibility Determination' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide 'Object-Based Algorithms' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Geometry-based analysis of scene objects before rasterization / - Compare each scene object against all other scene objects / - Determine visible parts based on virtual camera / - Rasterize the visible scene parts / For each object in sceneObjects. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |

| Technical commentary | This slide is about Object-Based Algorithms. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Geometry-based analysis of scene objects before rasterization / - Compare each scene object against all other scene objects / - Determine visible parts based on virtual camera / - Rasterize the visible scene parts / For each object in sceneObjects. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself       | Can you explain which samples/fragments are generated by 'Object-Based Algorithms'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide 'Image-Based Algorithms' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Pixel-based analysis of scene objects after rasterization / - Rasterize scene objects based on image resolution / - Investigate for each pixel which scene object is visible / For each pixel in outputRaster / // Determine which scene object is visible at this pixel. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations. |
| Technical commentary        | This slide is about Image-Based Algorithms. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Pixel-based analysis of scene objects after rasterization / - Rasterize scene objects based on image resolution / - Investigate for each pixel which scene object is visible / For each pixel in outputRaster / // Determine which scene object is visible at this pixel. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you explain which samples/fragments are generated by 'Image-Based Algorithms'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | <p>The slide '7.1 Object-Based Algorithms' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: 7.2 Binary Space Partitioning / 7.3 Warnock Algorithm / 7.4 Depth Buffer Algorithm / 7.5 Depth Buffer Extensions / 7.6 Ray Casting. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about 7.1 Object-Based Algorithms. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: 7.2 Binary Space Partitioning / 7.3 Warnock Algorithm / 7.4 Depth Buffer Algorithm / 7.5 Depth Buffer Extensions / 7.6 Ray Casting. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Source cue                  | Exploiting sorting and clipping                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Professor-style explanation | <p>The slide '7.1 Object-Based Algorithms' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: Exploiting sorting and clipping. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.</p> |
| Technical commentary        | <p>This slide is about 7.1 Object-Based Algorithms. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: Exploiting sorting and clipping. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in '7.1 Object-Based Algorithms'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | The slide 'Painter's Algorithm 1/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: Bob Ross - Grandeur of Summer. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                                                                                   |
| Technical commentary        | This slide is about Painter's Algorithm 1/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: Bob Ross - Grandeur of Summer. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you turn 'Painter's Algorithm 1/3' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Page 8                      | Painter's Algorithm 2/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source cue                  | - First algorithm for object-based visible polygon determination / - Input: set of polygons / - Output: rendering of visible polygons / - Procedure: simulate drawing process of a painting / 1. Sort polygons into list in back-to-front order                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Professor-style explanation | The slide 'Painter's Algorithm 2/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - First algorithm for object-based visible polygon determination / - Input: set of polygons / - Output: rendering of visible polygons / - Procedure: simulate drawing process of a painting / 1. Sort polygons into list in back-to-front order. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Technical commentary | This slide is about Painter's Algorithm 2/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - First algorithm for object-based visible polygon determination / - Input: set of polygons / - Output: rendering of visible polygons / - Procedure: simulate drawing process of a painting / 1. Sort polygons into list in back-to-front order. The slide groups them because one object or quantity is processed into another result used later in rendering. |
| Why it matters       | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Page 9                      | Painter's Algorithm 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | - Advantages / - Simple implementation / - No special graphics hardware necessary / - Disadvantages / - Works for polygons only instead of 3D scene objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Professor-style explanation | The slide 'Painter's Algorithm 3/3' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Advantages / - Simple implementation / - No special graphics hardware necessary / - Disadvantages / - Works for polygons only instead of 3D scene objects. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Painter's Algorithm 3/3. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Advantages / - Simple implementation / - No special graphics hardware necessary / - Disadvantages / - Works for polygons only instead of 3D scene objects. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you turn 'Painter's Algorithm 3/3' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|            |                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | The slide 'Weiler-Atherton Algorithm 1/3' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Clipping-based divide-and-conquer approach / - Input: set of polygons / - Output: set of visible polygon parts / - Procedure / 1. Sort polygons into list L in front-to-back order. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Weiler-Atherton Algorithm 1/3. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Clipping-based divide-and-conquer approach / - Input: set of polygons / - Output: set of visible polygon parts / - Procedure / 1. Sort polygons into list L in front-to-back order. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Weiler-Atherton Algorithm 1/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | The slide 'Weiler-Atherton Algorithm 2/3' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Example from original paper / - Z value order flipped / - Bold: clip polygon / - Gray: unoccluded parts. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Weiler-Atherton Algorithm 2/3. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Example from original paper / - Z value order flipped / - Bold: clip polygon / - Gray: unoccluded parts. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you decide what is accepted, rejected, or newly intersected in 'Weiler-Atherton Algorithm 2/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Page 12                     | Weiler-Atherton Algorithm 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Source cue                  | - Advantages / - Can handle lines and polygons / - Exact calculation of the visible polygons / - Can be used for wireframe rendering / with different edge styles                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Weiler-Atherton Algorithm 3/3' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Advantages / - Can handle lines and polygons / - Exact calculation of the visible polygons / - Can be used for wireframe rendering / with different edge styles. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion. |
| Technical commentary        | This slide is about Weiler-Atherton Algorithm 3/3. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Advantages / - Can handle lines and polygons / - Exact calculation of the visible polygons / - Can be used for wireframe rendering / with different edge styles. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | <p>The slide 'Back Face Culling 1/2' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Solves visibility determination for one convex, opaque scene object, / as its back faces are not visible / - Algorithm culls away polygons facing away from virtual camera / - Input: convex, opaque 3D scene object / - Output: set of front-facing polygons of input scene object. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Back Face Culling 1/2. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Solves visibility determination for one convex, opaque scene object, / as its back faces are not visible / - Algorithm culls away polygons facing away from virtual camera / - Input: convex, opaque 3D scene object / - Output: set of front-facing polygons of input scene object. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | <p>The slide 'Back Face Culling 2/2' explains rendering as a chain of object transformations. At the beginning there is scene information: models, vertices, primitives, attributes, camera state, and rendering state. The geometry part of the pipeline changes where the objects are and how they are represented; vertices become positioned data, vertices are assembled into primitives, and primitives are prepared for conversion to the image grid. The terms are successive representations in object-based rendering:</p> <ul style="list-style-type: none"> <li>- Advantages</li> <li>/ - Simple implementation</li> <li>/ - An average of 50% of the areas of a scene can be eliminated in this way</li> <li>/ - Reduces number of polygons to be processed, / thus reduces GPU transfers and speeds up the rendering process.</li> </ul> <p>Scene data becomes vertices, vertices become primitives, primitives become fragments, and only passing fragments update pixels. The important story is that the same scene information changes form several times. A triangle is first model data, then transformed geometry, then a projected primitive, then a set of fragments, and finally only some of those fragments become pixel updates. This is why the pipeline is not just a drawing diagram; it is the explanation for where image errors can enter.</p> |
| Technical commentary        | <p>This slide is about Back Face Culling 2/2. Scene or model data moves through a sequence of representations: vertices, primitives, fragments, tests, and framebuffer updates. Each named object is one stage in that conversion. The terms are successive representations in object-based rendering:</p> <ul style="list-style-type: none"> <li>- Advantages</li> <li>/ - Simple implementation</li> <li>/ - An average of 50% of the areas of a scene can be eliminated in this way</li> <li>/ - Reduces number of polygons to be processed, / thus reduces GPU transfers and speeds up the rendering process.</li> </ul> <p>Scene data becomes vertices, vertices become primitives, primitives become fragments, and only passing fragments update pixels.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Why it matters              | Pipeline understanding lets you localize rendering errors instead of guessing randomly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you name the input and output representation for 'Back Face Culling 2/2' in the rendering pipeline?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | <p>The slide 'Robert's Algorithm' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - First algorithm for object-based visible line determination / - Input: set of convex 3D scene objects / - Output: set of visible lines / - Procedure: perform for all scene objects the following steps / 1. Remove self-occluded surfaces through back-face culling. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |
| Technical commentary        | <p>This slide is about Robert's Algorithm. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - First algorithm for object-based visible line determination / - Input: set of convex 3D scene objects / - Output: set of visible lines / - Procedure: perform for all scene objects the following steps / 1. Remove self-occluded surfaces through back-face culling. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide 'Assessment Robert's Algorithm' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Advantages / - Determination of visible lines was particularly important / for presentation on vector screens / - Today used in non-photorealistic rendering / to generate line drawings. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p> |

| Technical commentary | This slide is about Assessment Robert's Algorithm. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Advantages / - Determination of visible lines was particularly important / for presentation on vector screens / - Today used in non-photorealistic rendering / to generate line drawings. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. |
| Why it matters       | Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself       | Can you explain which samples/fragments are generated by 'Assessment Robert's Algorithm'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Source cue                  | Hierarchical scene bisection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Professor-style explanation | The slide '7.2 Binary Space Partitioning' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: Hierarchical scene bisection. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about 7.2 Binary Space Partitioning. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: Hierarchical scene bisection. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you turn '7.2 Binary Space Partitioning' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|            |                                                                                                                                                                                                                                                                                      |

The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Spatial data structures are specialized / for organizing and storing scene data / - Types of spatial data structures / - Quad Trees: Optimize 2D data retrieval by dividing space it into four nodes / - Octrees: Optimize 3D data retrieval by dividing space it into eight nodes. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you turn 'Spatial Data Structures' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Page 19                     | BSP Trees 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | The slide 'BSP Trees 1/2' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - BSP Trees are Binary Space Partitioning trees / that recursively subdivide space into convex subsets through hyperplanes / - Key functions / - Space organization: divide 3D space into subspace represented as nodes / - Query efficiency: facilitate rapid querying like determining object visibility. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Technical commentary | This slide is about BSP Trees 1/2. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - BSP Trees are Binary Space Partitioning trees / that recursively subdivide space into convex subsets through hyperplanes / - Key functions / - Space organization: divide 3D space into subspace represented as nodes / - Query efficiency: facilitate rapid querying like determining object visibility. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself       | Can you decide whether 'BSP Trees 1/2' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | The slide 'BSP Trees 2/2' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Definition binary tree / - A binary tree is a tree with at most two child nodes per node / - Different traversal schemes for binary trees exist A X X / - In-order traversal: first left child, then root, then right child / B C Y C. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about BSP Trees 2/2. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Definition binary tree / - A binary tree is a tree with at most two child nodes per node / - Different traversal schemes for binary trees exist A X X / - In-order traversal: first left child, then root, then right child / B C Y C. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | The slide 'Node Data Structure' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Each node contains / - Hyperplane / - List of scene geometry associated with the node / Class BSPNode: / Declare plane as Plane. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Node Data Structure. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Each node contains / - Hyperplane / - List of scene geometry associated with the node / Class BSPNode: / Declare plane as Plane. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you decide whether 'Node Data Structure' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'BSP Tree Construction' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Choose a hyperplane from scene geometry for root node / and associate that plane with root node, split remaining geometry at plane / - Proceed recursively with the two resulting sets of scene geometries / and check each polygon against hyperplane / - Coinciding: associate with node. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |

|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about BSP Tree Construction. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Choose a hyperplane from scene geometry for root node / and associate that plane with root node, split remaining geometry at plane / - Proceed recursively with the two resulting sets of scene geometries / and check each polygon against hyperplane / - Coinciding: associate with node. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself       | Can you decide whether 'BSP Tree Construction' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Page 23                     | BSP Tree Construction - Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Source cue                  | 1 2 / 3 4 / A B E / 3 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Professor-style explanation | The slide 'BSP Tree Construction - Example' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: 1 2 / 3 4 / A B E / 3 1. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about BSP Tree Construction - Example. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: 1 2 / 3 4 / A B E / 3 1. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | <p>The slide 'BSP Tree Construction - Pseudo Code' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: Function buildBSPTree(BSPNode node, List of Polygons list) / // Select one polygon to use as a hyperplane / Polygon p = Get first polygon from list / Set node.plane to the plane of polygon p / Add polygon p to node.geometry. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about BSP Tree Construction - Pseudo Code. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: Function buildBSPTree(BSPNode node, List of Polygons list) / // Select one polygon to use as a hyperplane / Polygon p = Get first polygon from list / Set node.plane to the plane of polygon p / Add polygon p to node.geometry. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Professor-style explanation | <p>The slide 'Visibility Determination' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Visibility determination through modified depth-first traversal / respecting the current camera / - Tree traversal handles the entire scene geometry / - Drawing is done in analogy to painter's algorithm / - Traversing provides the necessary "strict back-to-front order". Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Visibility Determination. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Visibility determination through modified depth-first traversal / respecting the current camera / - Tree traversal handles the entire scene geometry / - Drawing is done in analogy to painter's algorithm / - Traversing provides the necessary "strict back-to-front order". Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | <p>Can you decide whether 'Visibility Determination' works per object, per image region, per ray, or per fragment?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | <p>The slide 'Visibility Determination - Pseudo Code' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: Function BSPHiddenSurfaceTraversal(BSPNode node, Point eye) / // Calculate the signed distance from the eye point to the partition plane / float distance = classifyPoint(node.plane, eye) / If distance &lt; 0 Then / // Eye-point is on the back side of the plane. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Visibility Determination - Pseudo Code. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: Function BSPHiddenSurfaceTraversal(BSPNode node, Point eye) / // Calculate the signed distance from the eye point to the partition plane / float distance = classifyPoint(node.plane, eye) / If distance &lt; 0 Then / // Eye-point is on the back side of the plane. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | <p>The slide 'BSP Tree Traversal - Example' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: B F / 4 1 2 / F B F B / 3 4 / F B F B. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p>                                                                                                                                                                                                                                          |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                        |

| Technical commentary | This slide is about BSP Tree Traversal - Example. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: B F / 4 1 2 / F B F B / 3 4 / F B F B. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                            |
| Check yourself       | Can you decide whether 'BSP Tree Traversal - Example' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                    |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Source cue                  | - Hyperplane selection influences tree balance and required geometry splits / - Two alternative approaches exist / - Planes can be derived from scene geometry / - Planes can be chosen freely / - Useful heuristics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Splitting Planes Selection' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Hyperplane selection influences tree balance and required geometry splits / - Two alternative approaches exist / - Planes can be derived from scene geometry / - Planes can be chosen freely / - Useful heuristics. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Splitting Planes Selection. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Hyperplane selection influences tree balance and required geometry splits / - Two alternative approaches exist / - Planes can be derived from scene geometry / - Planes can be chosen freely / - Useful heuristics. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you turn 'Splitting Planes Selection' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|            |                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | <p>The slide 'Traversal Optimization' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test:</p> <ul style="list-style-type: none"> <li>- Sub-trees can be skipped during traversal if content is outside view frustum</li> <li>- Testing is done by checking 8 corner points of 3D view frustum</li> <li>- If there are two points on different sides, then the subtree is traversed</li> <li>- If all points are in one subspace, then the other subspace does not have to be traversed (view-frustum culling).</li> </ul> <p>Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Traversal Optimization. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test:</p> <ul style="list-style-type: none"> <li>- Sub-trees can be skipped during traversal if content is outside view frustum</li> <li>- Testing is done by checking 8 corner points of 3D view frustum</li> <li>- If there are two points on different sides, then the subtree is traversed</li> <li>- If all points are in one subspace, then the other subspace does not have to be traversed (view-frustum culling).</li> </ul> <p>Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | <p>Can you decide whether 'Traversal Optimization' works per object, per image region, per ray, or per fragment?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | The slide 'Assessment BSP Trees' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Advantages / - Simple implementation / - Do not need a depth buffer / - Applicable to static and dynamic scenes / (static scene geometry precalculated, dynamic objects inserted). Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Assessment BSP Trees. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Advantages / - Simple implementation / - Do not need a depth buffer / - Applicable to static and dynamic scenes / (static scene geometry precalculated, dynamic objects inserted). Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Assessment BSP Trees'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide '7.3 Warnock Algorithm' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: Image-based divide-and-conquer strategy. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about 7.3 Warnock Algorithm. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: Image-based divide-and-conquer strategy. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | The slide 'Warnock Algorithm' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Hybrid object- and image-based divide-and-conquer approach / - Input: set of polygons and viewport / - Output: set of visible polygon parts / - Procedure: exploit spatial coherence of projected polygons to divide viewport / - Divide viewport recursively into squared regions. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Warnock Algorithm. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Hybrid object- and image-based divide-and-conquer approach / - Input: set of polygons and viewport / - Output: set of visible polygon parts / - Procedure: exploit spatial coherence of projected polygons to divide viewport / - Divide viewport recursively into squared regions. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Check yourself              | Can you decide whether 'Warnock Algorithm' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | <p>The slide 'Region-Based Visibility Determination' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: <math>R \cap P \neq \emptyset</math> / Case 1 / - Given viewport region <math>R</math> and set of polygons <math>P</math>, for the following / cases visibility determination can be considered trivial / - Case 1: All polygons in <math>P</math> are outside of <math>R</math> <math>R \cap P = \emptyset</math>. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Region-Based Visibility Determination. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: <math>R \cap P \neq \emptyset</math> / Case 1 / - Given viewport region <math>R</math> and set of polygons <math>P</math>, for the following / cases visibility determination can be considered trivial / - Case 1: All polygons in <math>P</math> are outside of <math>R</math> <math>R \cap P = \emptyset</math>. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | <p>The slide 'Procedure' explains how camera geometry turns a 3D scene into image coordinates. In view space, objects are described relative to the camera. The projection matrix then maps that camera-centered geometry into clip space, where the viewing volume and clipping boundaries can be handled consistently. Perspective projection uses the homogeneous coordinate so that the later divide by w creates foreshortening: farther objects occupy less image space. Orthographic projection removes that depth-based size change and keeps parallel structures visually parallel. The terms describe camera-to-screen mapping:</p> <ul style="list-style-type: none"> <li>- Start with entire viewport region R</li> <li>- Subdivide R into four equal subregions</li> <li>- Terminate if subregion size matches pixel size</li> <li>- Classify subregions based on trivial cases</li> <li>- If subregion matches trivial cases: resolve.</li> </ul> <p>View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport. The object chain is view-space position, projection matrix, clip coordinate, normalized device coordinate, and viewport coordinate. The slide is therefore connecting camera setup, visual appearance, and the numeric coordinate pipeline that rasterization later consumes.</p> |
| Technical commentary        | <p>This slide is about Procedure. The projection objects on the slide convert view-space geometry into clip coordinates, normalized coordinates, and finally screen-related positions. The terms describe camera-to-screen mapping:</p> <ul style="list-style-type: none"> <li>- Start with entire viewport region R</li> <li>- Subdivide R into four equal subregions</li> <li>- Terminate if subregion size matches pixel size</li> <li>- Classify subregions based on trivial cases</li> <li>- If subregion matches trivial cases: resolve.</li> </ul> <p>View-space geometry is mapped by a projection matrix, clipped, divided into normalized coordinates, and finally mapped to a viewport.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Why it matters              | Projection controls both image composition and depth precision, so it affects visibility and rasterization later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you explain how 'Procedure' changes positions before rasterization?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Professor-style explanation | <p>The slide 'Pseudo Code' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test:</p> <pre> Procedure warnockHSR(Polygons list, Viewport vp) / If isSimple(list, vp) Then // Base case: Simple enough scenario to draw directly / drawPolygons(list) / Else. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. </pre>                                                                                                                                                                                                                                                                                             |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Pseudo Code. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: Procedure warnockHSR(Polygons list, Viewport vp) / If isSimple(list, vp) Then / // Base case: Simple enough scenario to draw directly / drawPolygons(list) / Else. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself       | Can you decide whether 'Pseudo Code' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | The slide 'Assessment Warnock Algorithm' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Advantages / - Efficient for large polygons by exploiting spatial coherence / - Easy to implement through recursive programming / - Disadvantages / - Restriction to polygons as primitives. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Assessment Warnock Algorithm. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Advantages / - Efficient for large polygons by exploiting spatial coherence / - Easy to implement through recursive programming / - Disadvantages / - Restriction to polygons as primitives. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you decide whether 'Assessment Warnock Algorithm' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | The slide '7.4 Depth Buffer Algorithm' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: Exploiting image storage for visibility determination. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about 7.4 Depth Buffer Algorithm. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: Exploiting image storage for visibility determination. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in '7.4 Depth Buffer Algorithm'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | The slide 'Depth Buffer Algorithm 1/3' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Image-based visibility determination algorithm / that exploits extra graphics memory called depth buffer (= z-buffer) / - Depth buffer / - Depth buffer is a 2D raster that contains depth values / - Depth value calculation happens during rasterization. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |

| Technical commentary | This slide is about Depth Buffer Algorithm 1/3. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Image-based visibility determination algorithm / that exploits extra graphics memory called depth buffer (= z-buffer) / - Depth buffer / - Depth buffer is a 2D raster that contains depth values / - Depth value calculation happens during rasterization. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. |
| Why it matters       | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Check yourself       | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Depth Buffer Algorithm 1/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Page 39                     | Depth Buffer Algorithm 2/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | - Depth buffer algorithm follows occlusion culling principle / Function <code>occlusionCulling(List of Polygons scene)</code> / Initialize an <code>OcclusionRepresentation OR</code> / For each object <code>obj</code> in scene / If <code>obj</code> is occluded by <code>OR</code> Then                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Depth Buffer Algorithm 2/3' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Depth buffer algorithm follows occlusion culling principle / Function <code>occlusionCulling(List of Polygons scene)</code> / Initialize an <code>OcclusionRepresentation OR</code> / For each object <code>obj</code> in scene / If <code>obj</code> is occluded by <code>OR</code> Then. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Depth Buffer Algorithm 2/3. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Depth buffer algorithm follows occlusion culling principle / Function <code>occlusionCulling(List of Polygons scene)</code> / Initialize an <code>OcclusionRepresentation OR</code> / For each object <code>obj</code> in scene / If <code>obj</code> is occluded by <code>OR</code> Then. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Depth Buffer Algorithm 2/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Page 40                     | Depth Buffer Algorithm 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Source cue                  | - Depth buffer algorithm performs depth testing for each fragment / - Depth buffer is initialized with background value (e.g., $z = 1$ ) / - For every scene object / - Rasterize scene object / - For each fragment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Depth Buffer Algorithm 3/3' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Depth buffer algorithm performs depth testing for each fragment / - Depth buffer is initialized with background value (e.g., $z = 1$ ) / - For every scene object / - Rasterize scene object / - For each fragment. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Depth Buffer Algorithm 3/3. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Depth buffer algorithm performs depth testing for each fragment / - Depth buffer is initialized with background value (e.g., $z = 1$ ) / - For every scene object / - Rasterize scene object / - For each fragment. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Depth Buffer Algorithm 3/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Page 41                     | Pseudo Code - Depth Buffer Test                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Source cue                  | Function zBufferHSR(List of Geometry list) // Initialize z-buffer and color buffer for each pixel on the screen / For x from 0 to Width / For y from 0 to Height / Set depthbuffer[x][y] to 1.0 // Maximum depth value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Pseudo Code - Depth Buffer Test' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: Function</p> <pre>zBufferHSR(List of Geometry list) / // Initialize z-buffer and color buffer for each pixel on the screen / For x from 0 to Width / For y from 0 to Height / Set depthbuffer[x][y] to 1.0 // Maximum depth value.</pre> <p>Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.</p> |
| Technical commentary        | <p>This slide is about Pseudo Code - Depth Buffer Test. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: Function</p> <pre>zBufferHSR(List of Geometry list) / // Initialize z-buffer and color buffer for each pixel on the screen / For x from 0 to Width / For y from 0 to Height / Set depthbuffer[x][y] to 1.0 // Maximum depth value.</pre> <p>Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Pseudo Code - Depth Buffer Test'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | <p>The slide 'OpenGL Depth Buffer' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution:</p> <ul style="list-style-type: none"> <li>- OpenGL depth buffer: initialization and activation /</li> <li>- Depth values are limited to <math>[0, 1]</math> (0: near-plane, 1: far-plane) /</li> <li>- Depth test must be explicitly activated /</li> <li>- Depth test comparison function can be changed / Function <code>init()</code>.</li> </ul> <p>Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.</p> |
| Technical commentary        | <p>This slide is about OpenGL Depth Buffer. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution:</p> <ul style="list-style-type: none"> <li>- OpenGL depth buffer: initialization and activation /</li> <li>- Depth values are limited to <math>[0, 1]</math> (0: near-plane, 1: far-plane) /</li> <li>- Depth test must be explicitly activated /</li> <li>- Depth test comparison function can be changed / Function <code>init()</code>.</li> </ul> <p>Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'OpenGL Depth Buffer'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide 'Depth Buffer Precision' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution:</p> <ul style="list-style-type: none"> <li>- Depth buffer precision is limited by its bit-depth (e.g., 16-bit, 24-bit, 32-bit), / which determines how finely depth can be distinguished /</li> <li>- Depth buffer precision is not linear: denser at near- and sparser at far- / clipping plane <math>\Rightarrow</math> depth conflicts can occur especially at greater distances / Nvidia Blog.</li> </ul> <p>Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.</p> |
| Technical commentary        | <p>This slide is about Depth Buffer Precision. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. | Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Depth Buffer Precision'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Page 44                     | Z-Fighting 1/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Source cue                  | - Z-fighting occurs when two or more objects are very close together in depth / - Depth buffer can't consistently resolve which one is closer / causing flickering or overlapping artifacts in the rendered scene                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | The slide 'Z-Fighting 1/2' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Z-fighting occurs when two or more objects are very close together in depth / - Depth buffer can't consistently resolve which one is closer / causing flickering or overlapping artifacts in the rendered scene. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Z-Fighting 1/2. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Z-fighting occurs when two or more objects are very close together in depth / - Depth buffer can't consistently resolve which one is closer / causing flickering or overlapping artifacts in the rendered scene. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Z-Fighting 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | <p>The slide 'Z-Fighting 2/2' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution:</p> <ul style="list-style-type: none"> <li>- Mitigation through depth buffer properties /</li> <li>- Use higher precision buffers by switching from 24-bit to 32-bit depth /</li> <li>- Adjust near and far planes: bringing near plane out- and far plane inwards /</li> </ul> <p>reduces the depth range, improving effective depth buffer precision /</p> <ul style="list-style-type: none"> <li>- Mitigating through rendering properties. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.</li> </ul> |
| Technical commentary        | <p>This slide is about Z-Fighting 2/2. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. | Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Z-Fighting 2/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Assessment Depth Buffering' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Advantages / - Easy implementation / - No presorting of scene objects required / $\Rightarrow$ Object evaluation can be performed in any order / - Not limited to polygonal geometries. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Assessment Depth Buffering. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Advantages / - Easy implementation / - No presorting of scene objects required / $\Rightarrow$ Object evaluation can be performed in any order / - Not limited to polygonal geometries. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Assessment Depth Buffering'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Page 47                     | 7.5 Depth Buffer Extensions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | The slide '7.5 Depth Buffer Extensions' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: How to render semi-transparent scene objects, and how to generate halos. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.                                                                                                                 |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Professor-style explanation | The slide 'Semi-Transparent Objects 1/2' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Rendering of semi-transparent objects requires special handling / - Opaque and semi-transparent geometry need to be separated / - Opaque geometry is rendered first, semi-transparent blended on top / Function draw(Vector scene) / // Clear the framebuffer to prepare for new drawing. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Semi-Transparent Objects 1/2. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Rendering of semi-transparent objects requires special handling / - Opaque and semi-transparent geometry need to be separated / - Opaque geometry is rendered first, semi-transparent blended on top / Function draw(Vector scene) / // Clear the framebuffer to prepare for new drawing. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Semi-Transparent Objects 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Page 49                     | Semi-Transparent Objects 2/2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Source cue                  | - Issue: correct transparency without presorting of scene objects not possible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Professor-style explanation | The slide 'Semi-Transparent Objects 2/2' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Issue: correct transparency without presorting of scene objects not possible. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Technical commentary        | This slide is about Semi-Transparent Objects 2/2. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Issue: correct transparency without presorting of scene objects not possible. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you turn 'Semi-Transparent Objects 2/2' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Page 50                     | Order-Independent Transparency 1/4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | The slide 'Order-Independent Transparency 1/4' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Order-independent transparency exploits depth peeling to avoid sorting / - Depth peeling peels away depth layers one-by-one in front-to-back order / - Extract nearest fragments with smallest z values in first rendering pass / - Extract next further fragments in each subsequent rendering pass / - The nth rendering pass delivers the fragments to the nth depth plane. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Technical commentary | This slide is about Order-Independent Transparency 1/4. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Order-independent transparency exploits depth peeling to avoid sorting / - Depth peeling peels away depth layers one-by-one in front-to-back order / - Extract nearest fragments with smallest z values in first rendering pass / - Extract next further fragments in each subsequent rendering pass / - The nth rendering pass delivers the fragments to the nth depth plane. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself       | Can you decide whether 'Order-Independent Transparency 1/4' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide 'Order-Independent Transparency 2/4' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Illustration of subsequent layers / Layer 0 Layer 1 Layer 2 / 0 depth 1 0 depth 1 0 depth 1. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Order-Independent Transparency 2/4. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Illustration of subsequent layers / Layer 0 Layer 1 Layer 2 / 0 depth 1 0 depth 1 0 depth 1. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | The slide 'Order-Independent Transparency 3/4' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - 1st pass / - Render scene with conventional depth test (GL_LESS) / - Store resulting depth layer in Z-Buffer A / - Store resulting color layer as Layer 0 / - 2nd pass. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image. |
| Technical commentary        | This slide is about Order-Independent Transparency 3/4. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - 1st pass / - Render scene with conventional depth test (GL_LESS) / - Store resulting depth layer in Z-Buffer A / - Store resulting color layer as Layer 0 / - 2nd pass. Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you name the OpenGL object, state, shader stage, or buffer involved in 'Order-Independent Transparency 3/4'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Page 53                     | Order-Independent Transparency 4/4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Source cue                  | 1 layer 2 layers / 3 layers 4 layers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Professor-style explanation | The slide 'Order-Independent Transparency 4/4' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: 1 layer 2 layers / 3 layers 4 layers. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Technical commentary        | This slide is about Order-Independent Transparency 4/4. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: 1 layer 2 layers / 3 layers 4 layers. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Generating Haloes 1/2' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Halo: circle of light around sun or moon caused by ice crystals in the air; [...]; / a distinguishing zone surrounding a central object / - Haloes as wireframe illustration tools result / in better spatial comprehension / - Add highlights to foreground lines. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Generating Haloes 1/2. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Halo: circle of light around sun or moon caused by ice crystals in the air; [...]; / a distinguishing zone surrounding a central object / - Haloes as wireframe illustration tools result / in better spatial comprehension / - Add highlights to foreground lines. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Generating Haloes 1/2'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Professor-style explanation | <p>The slide 'Generating Haloes 2/2' explains how OpenGL exposes the rendering pipeline through explicit objects and state. A context owns the current rendering state; buffers hold vertex, index, texture, or pixel data; shader programs define programmable processing; textures and samplers provide sampled data; framebuffers receive the result. OpenGL does not render from intention, it renders from the objects that are bound and the state that is active at the moment of the draw call. The terms connect CPU-side API control with GPU execution: - Proceeding / - Render wireframe model with thick lines into depth buffer / without writing to the color buffer <math>\Rightarrow</math> depth image contains thick lines / - Render wireframe model with thin lines into color buffer / <math>\Rightarrow</math> Lines of foreground surfaces have a "safety margin". Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written. The concrete relation is API command, GPU resource, shader interface, and visible result. A small mismatch in this relation, such as a wrong buffer layout, missing uniform, wrong texture unit, or disabled depth test, can produce a perfectly valid draw call with a completely wrong image.</p> |
| Technical commentary        | <p>This slide is about Generating Haloes 2/2. The OpenGL objects and calls shown here control GPU state, bound resources, shader interfaces, buffer contents, or framebuffer access at draw time. The terms connect CPU-side API control with GPU execution: - Proceeding / - Render wireframe model with thick lines into depth buffer / without writing to the color buffer <math>\Rightarrow</math> depth image contains thick lines / - Render wireframe model with thin lines into color buffer / <math>\Rightarrow</math> Lines of foreground surfaces have a "safety margin". Objects, bindings, shader interfaces, buffers, and framebuffer state determine what data is processed and where results are written.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Why it matters              | <p>OpenGL bugs are usually state, binding, shader-interface, or buffer-layout bugs, so API details matter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Professor-style explanation | <p>The slide '7.6 Ray Casting' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: Shooting rays to determine visibility. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p>                                                                                                                                                                                                                                                                                                                                                                         |

|                      |                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about 7.6 Ray Casting. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: Shooting rays to determine visibility. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                               |
| Check yourself       | Can you decide whether '7.6 Ray Casting' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                    |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | The slide 'Ray Casting Principle' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Image-based visibility determination algorithm exploiting ray intersections / - Ray initialization - initialize ray from viewpoint through each pixel / (ray generation) / - Intersection calculation - find object intersection closest to camera / (ray intersection). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Ray Casting Principle. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Image-based visibility determination algorithm exploiting ray intersections / - Ray initialization - initialize ray from viewpoint through each pixel / (ray generation) / - Intersection calculation - find object intersection closest to camera / (ray intersection). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | <p>The slide 'Ray Initialization 1/3' explains the moment where continuous geometry becomes a discrete image problem. A mathematical line or triangle is not made of pixels, but the screen is a grid of samples. Rasterization decides which samples are covered by the projected primitive and creates fragments for those samples. At the same time, values attached to the primitive, such as depth, color, normals, or texture coordinates, are interpolated so that each fragment has the data needed for shading. The terms describe sample generation: - Ray is defined by origin and direction / - Mathematically parameterized as a 3D line via <math>t / s - e / - p \ t = e + t \ s / s - e</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments. The important distinction is that rasterization creates candidates. A fragment exists because a primitive covered a sample, but final visibility still depends on depth testing, stencil testing, blending, masking, and framebuffer operations.</p>                 |
| Technical commentary        | <p>This slide is about Ray Initialization 1/3. The rasterization objects on the slide convert ideal geometric primitives into covered samples or fragments with interpolated attributes. The terms describe sample generation: - Ray is defined by origin and direction / - Mathematically parameterized as a 3D line via <math>t / s - e / - p \ t = e + t \ s / s - e</math>. A continuous primitive is tested against the pixel grid, covered samples become fragments, and interpolated attributes travel with those fragments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Rasterization determines fragment generation; without it, shading and fragment tests have nothing to operate on.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Professor-style explanation | <p>The slide 'Ray Initialization 2/3' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - How can we find <math>s</math>? / - Assumption: we have a simplified camera model / - Positioned in <math>e</math> / - Orthonormal base <math>\{u, v, w\}</math> / - Orthonormal: orthogonal + normalized. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |

| Technical commentary | This slide is about Ray Initialization 2/3. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - How can we find s? / - Assumption: we have a simplified camera model / - Positioned in e / - Orthonormal base {u, v, w} / - Orthonormal: orthogonal + normalized. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself       | Can you decide whether 'Ray Initialization 2/3' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Page 60                     | Ray Initialization 3/3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Source cue                  | - Definition of the pixel grid with $n \times n$ pixels / $x\ y$ / - Size of the pixel raster is $r - l \times t - b$ / - Pixel spacing is / - x-coordinate: $(r - l)/n$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Professor-style explanation | The slide 'Ray Initialization 3/3' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Definition of the pixel grid with $n \times n$ pixels / $x\ y$ / - Size of the pixel raster is $r - l \times t - b$ / - Pixel spacing is / - x-coordinate: $(r - l)/n$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Ray Initialization 3/3. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Definition of the pixel grid with $n \times n$ pixels / $x\ y$ / - Size of the pixel raster is $r - l \times t - b$ / - Pixel spacing is / - x-coordinate: $(r - l)/n$ . Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you state the coordinate space before and after 'Ray Initialization 3/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|            |                                                                                                                                                                                                                 |

| Professor-style explanation | The slide 'Intersection Calculation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Find smallest positive $t$ for which $p(t)$ is an intersection / - Simple procedure / - Iterate over all scene objects and calculate intersections / - Sort intersections / - Select intersection with smallest $t$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Intersection Calculation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Find smallest positive $t$ for which $p(t)$ is an intersection / - Simple procedure / - Iterate over all scene objects and calculate intersections / - Sort intersections / - Select intersection with smallest $t$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you turn 'Intersection Calculation' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Source cue                  | - Find set of all points with $f(x, y, z) = 0$ / - Examples: plane, sphere, quadrics, ... / $n = (A, B, C)$ / $c = (x, y, z)$ / $c \cdot c \cdot c$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Professor-style explanation | The slide 'Implicit Surface Intersection Calculation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Find set of all points with $f(x, y, z) = 0$ / - Examples: plane, sphere, quadrics, ... / $n = (A, B, C)$ / $c = (x, y, z)$ / $c \cdot c \cdot c$ . The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Implicit Surface Intersection Calculation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Find set of all points with $f(x, y, z) = 0$ / - Examples: plane, sphere, quadrics, ... / $n = (A, B, C)$ / $c = (x, y, z)$ / $c \cdot c \cdot c$ . The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Exploit barycentric coordinates                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Professor-style explanation | The slide 'Intersection Calculation - Triangle' explains how geometric objects move through coordinate systems. A point has a location, a vector has a direction and magnitude, a normal describes surface orientation, and a coordinate frame defines how these quantities are measured. A transformation matrix changes the description of these objects: translation moves points, rotation changes orientation, scaling changes size, and composition combines several operations into one matrix product. The terms describe a coordinate-space conversion: - Idea: find intersection with plane which embeds triangle, / and test whether intersection lies inside triangle / 1. Calculate intersection with plane / through implicit surface intersection calculation / 2. Exploit barycentric coordinates. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space. The central relation is source space, transformation, and target space. In computer graphics this relation is everywhere: object space becomes world space, world space becomes view space, and view space becomes clip space. A formula is only meaningful after the two coordinate spaces around it are clear. |
| Technical commentary        | This slide is about Intersection Calculation - Triangle. The transformation objects on the slide move points, vectors, or coordinate frames from one space into another using matrices or affine operations. The terms describe a coordinate-space conversion: - Idea: find intersection with plane which embeds triangle, / and test whether intersection lies inside triangle / 1. Calculate intersection with plane / through implicit surface intersection calculation / 2. Exploit barycentric coordinates. Input positions or vectors are transformed by matrices so the same object can be expressed in model, world, view, or clip space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Why it matters              | A wrong coordinate-space assumption can make correct formulas produce wrong images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | Can you state the coordinate space before and after 'Intersection Calculation - Triangle'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | <p>The slide 'Pseudo Code - Analytic Intersection Computation' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: Function <code>castRay(List sceneObjects, Window win, Camera cam)</code> // Iterate over each pixel on the window / For x from 0 to win.width / For y from 0 to win.height / Initialize ray <code>r = calculateRay(x, y, win, cam)</code> // Calculate ray from camera through pixel (x, y). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Pseudo Code - Analytic Intersection Computation. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: Function <code>castRay(List sceneObjects, Window win, Camera cam)</code> // Iterate over each pixel on the window / For x from 0 to win.width / For y from 0 to win.height / Initialize ray <code>r = calculateRay(x, y, win, cam)</code> // Calculate ray from camera through pixel (x, y). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | <p>The slide 'Pseudo Code - Iterative Intersection Calculation (Ray Marching)' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Ray march in <math>\epsilon</math> steps and check all scene objects for intersection / Function intersect(const Ray&amp; ray, const List of SceneObjects&amp; sceneObjects) const / Initialize t as 0.0 // Starting point for ray parameter / Initialize epsilon as 0.01 // Small increment for ray parameter / // Loop to incrementally trace the ray through the scene. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Pseudo Code - Iterative Intersection Calculation (Ray Marching). The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Ray march in <math>\epsilon</math> steps and check all scene objects for intersection / Function intersect(const Ray&amp; ray, const List of SceneObjects&amp; sceneObjects) const / Initialize t as 0.0 // Starting point for ray parameter / Initialize epsilon as 0.01 // Small increment for ray parameter / // Loop to incrementally trace the ray through the scene. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | <p>Visibility decides which generated candidates are actually seen from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | <p>The slide 'Assessment Ray Casting' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Advantages / - Image-precise algorithm that support all types of scene objects / - Analytic intersection calculation possible / - Can be parallelized and supported by graphics hardware / - Disadvantages. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.</p> |
| Technical commentary        | <p>This slide is about Assessment Ray Casting. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Advantages / - Image-precise algorithm that support all types of scene objects / - Analytic intersection calculation possible / - Can be parallelized and supported by graphics hardware / - Disadvantages. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | <p>The slide 'but are crucial for accurate visibility determination' explains clipping as a geometric boundary operation. A line segment, polygon, or triangle is compared with a window, plane, or volume. The part inside the valid region survives, the part outside is removed, and a primitive crossing the boundary receives newly computed intersection points. The terms describe boundary decisions: - Visibility determination ensures only scene objects visible from camera are rendered / - Effective visibility determination is crucial for rendering efficiency and visual accuracy / - Object-based algorithms perform geometry-based analysis prior to rasterization / - Examples include the Painter's Algorithm, Weiler-Atherton, and Back Face Culling / - These methods often suffer from higher complexity and can be poorly parallelizable. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary. The objects involved are the original primitive, the clipping boundary, an inside/outside classification, intersection points, and the resulting clipped primitive. The core idea is not simply deleting geometry; clipping can reshape geometry so that the rasterizer receives only the meaningful visible portion.</p> |
| Technical commentary        | <p>This slide is about but are crucial for accurate visibility determination. The clipping objects on the slide classify geometry against boundaries and produce accepted, rejected, or newly intersected primitive pieces. The terms describe boundary decisions: - Visibility determination ensures only scene objects visible from camera are rendered / - Effective visibility determination is crucial for rendering efficiency and visual accuracy / - Object-based algorithms perform geometry-based analysis prior to rasterization / - Examples include the Painter's Algorithm, Weiler-Atherton, and Back Face Culling / - These methods often suffer from higher complexity and can be poorly parallelizable. A primitive is classified against a clipping region, rejected if outside, preserved if inside, or cut at intersections if it crosses a boundary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Why it matters              | <p>Clipping decides what geometry is allowed to reach rasterization and can create new boundary vertices.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Check yourself              | <p>Can you decide what is accepted, rejected, or newly intersected in 'but are crucial for accurate visibility determination'?</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Source cue                  | <p>No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Professor-style explanation | <p>The slide 'Literature and other sources used in this chapter' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Technical commentary        | This slide is about Literature and other sources used in this chapter. The slide lists source material or chapter references that support the technical content and give names for further reading. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Why it matters              | Reference slides provide the source trail for definitions, algorithms, and deeper explanations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you identify which source or topic 'Literature and other sources used in this chapter' points to for deeper study?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Page 69                     | Practice, Addison-Wesley.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

White paper,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Professor-style explanation | The slide 'Practice, Addison-Wesley.' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - Text Books / - Foley J., van Dam, A., Feiner, S. (2013). Computer Graphics: Principles and / Practice, Addison-Wesley. / - Papers / - Everitt, C. (2001). Interactive order-independent transparency. White paper,. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Practice, Addison-Wesley.. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - Text Books / - Foley J., van Dam, A., Feiner, S. (2013). Computer Graphics: Principles and / Practice, Addison-Wesley. / - Papers / - Everitt, C. (2001). Interactive order-independent transparency. White paper,. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Check yourself              | Can you turn 'Practice, Addison-Wesley.' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 07.1 Object-Based Algorithms

Source location: Section 7.1

### Commentary

Object-based visibility algorithms reason about geometry before or while comparing surfaces. They can sort, split, or reject objects based on spatial relations. This is different from simply letting every fragment fight in the depth buffer.

The value of object-based reasoning is reducing work or establishing correct order. The difficulty is that geometry can overlap in complicated ways, so simple global ordering is not always possible.

## **Mental model**

Object-based visibility tries to solve visibility with geometry before final pixels are written.

## **Check yourself**

Why can intersecting polygons make simple depth sorting fail?

## **07.2 Binary Space Partitioning**

Source location: Section 7.2

### **Commentary**

A BSP tree recursively divides space with planes. Once built, it can help traverse geometry in a view-dependent order. This is useful for visibility and ordering because the tree encodes spatial relationships.

The cost is preprocessing and possible splitting of geometry. BSP is a good example of trading memory and setup work for faster or more structured visibility decisions later.

## **Mental model**

A BSP tree stores a recursive answer to 'which side of this plane is the geometry on?'

## **Check yourself**

Why can building a BSP tree require splitting polygons?

## **07.3 Warnock Algorithm**

Source location: Section 7.3

### **Commentary**

Warnock's algorithm works in image space by subdividing regions until visibility is simple enough to decide. If a region is ambiguous, split it. If it is simple, fill it.

This illustrates a general graphics strategy: recursively reduce a hard global problem into smaller local problems. The algorithm is less central in modern OpenGL practice than the depth buffer, but it helps contrast image-space and object-space approaches.

## **Mental model**

When a region is too complicated, subdivide until the answer becomes simple.

## **Check yourself**

What makes Warnock's algorithm image-space rather than object-space?

## **07.4 Depth Buffer Algorithm**

Source location: Section 7.4

## Commentary

The depth buffer stores the closest accepted depth at each sample or pixel. For each fragment, compare its depth to the stored depth. If it passes, update the color and depth; otherwise discard it.

The strength of the depth buffer is simplicity and hardware efficiency. The weakness is precision: depth values are finite, and projection distributes precision unevenly. Bad near/far settings can create z-fighting.

## Mental model

The depth buffer is a per-sample competition for closest visible fragment.

## Check yourself

Why should the near plane not be unnecessarily close to the camera?

# 07.5 Depth Extensions and Ray Casting

Source location: Sections 7.5-7.6

## Commentary

Depth buffer extensions refine or adapt depth-based visibility, for example by handling precision, transparency, or multiple layers more carefully. Standard depth testing alone is not a complete solution for every visibility situation.

Ray casting takes the opposite direction from rasterization: for each image sample, cast a ray into the scene and find the closest intersection. This naturally solves primary visibility but requires intersection work instead of raster coverage work.

## Mental model

Rasterization pushes primitives to pixels; ray casting pulls visibility from pixels into the scene.

## Check yourself

Why is transparency harder than opaque nearest-surface visibility?

# End-of-lecture summary

If you remember only one thing from Lecture 07, remember this: This lecture asks which surfaces are visible from a viewpoint. Rasterization can generate many fragment candidates, but visibility decides which ones should affect the image.

Before moving on, you should be able to explain the lecture without reading slide bullets aloud. Use the vocabulary from the slides, but add causal links: why a step exists, what data it consumes, what it produces, and what can go wrong.

# Lecture 08 - Local Illumination

This lecture explains how visible surface points receive color from local light, material, normal, and view information. It is about shading a point, not solving all global light transport.

## How to read this lecture

- Read the section commentary before looking at the raw slide bullets.
- Use the mental model as the short version you should remember.
- Answer the check question without notes before continuing.

## Per-slide commentary

Each extracted slide page gets its own note. Use this section as the spoken commentary that the terse slide deck is missing.

| Page 1                      | Visual or title slide                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source cue                  | No object-level text was extracted from this page; the page is primarily title, image, diagram, or layout content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Professor-style explanation | The slide 'Visual or title slide' is primarily a visual, title, transition, or diagram page rather than a text-heavy concept slide. Its role is to place the next concept into the lecture flow and give a visual anchor for the topic that follows. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text. In the surrounding lecture sequence, this kind of page usually marks a shift of attention: from one pipeline stage to another, from a general idea to an algorithm, or from theory to an implementation detail. |
| Technical commentary        | This slide is about Visual or title slide. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The extracted text does not expose object-level labels for this page. Within the lecture flow, the page functions as a visual, diagram, or title transition, so its connection is established by the surrounding slides rather than by readable bullet text.                                                                                                                                                                                                                                                                                              |
| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you turn 'Visual or title slide' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Page 2                      | Local Illumination                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Source cue                  | - Illumination is the process of simulating light interactions in a virtual scene / - Requires light and material properties / - Achieved through illumination model / - Essential for scene perception / without illumination with illumination                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | The slide 'Local Illumination' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Illumination is the process of simulating light interactions in a virtual scene / - Requires light and material properties / - Achieved through illumination model / - Essential for scene perception / without illumination with illumination. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Local Illumination. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Illumination is the process of simulating light interactions in a virtual scene / - Requires light and material properties / - Achieved through illumination model / - Essential for scene perception / without illumination with illumination. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Local Illumination'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Professor-style explanation | The slide '8.1 Physics of Light' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: 8.2 Light Sources / 8.3 Material Models / 8.4 Phong Illumination Model / 8.5 Shading. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Technical commentary | This slide is about 8.1 Physics of Light. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: 8.2 Light Sources / 8.3 Material Models / 8.4 Phong Illumination Model / 8.5 Shading. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. |
| Why it matters       | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                          |
| Check yourself       | Can you identify the normal, light vector, view vector, and material term relevant to '8.1 Physics of Light'?                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide '8.1 Physics of Light' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: Understanding light in the real world. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about 8.1 Physics of Light. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: Understanding light in the real world. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | The slide 'Electromagnetic Radiation' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Electromagnetic radiation is defined by a spectrum of wavelengths / Wave length $\lambda$ / - Visible light is subset of electromagnetic spectrum between 400 and 700nm, / which humans perceive as colors. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Electromagnetic Radiation. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Professor-style explanation | The slide 'Visible Light' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: 1000 nm / Infrared / Radio / 700 nm / TV Red. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |

| Professor-style explanation | The slide 'Visible Light' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: 1000 nm / Infrared / Radio / 700 nm / TV Red. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Visible Light. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: 1000 nm / Infrared / Radio / 700 nm / TV Red. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | <p>The slide 'Light Spectra' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Different light sources have different light spectra / - Intensity differs based on wavelength in visible spectrum / [<a href="http://www.micro.magnet.fsu.edu/optics/lightandcolor/sources.html">http://www.micro.magnet.fsu.edu/optics/lightandcolor/sources.html</a>]. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type.</p> |
| Technical commentary        | <p>This slide is about Light Spectra. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Different light sources have different light spectra / - Intensity differs based on wavelength in visible spectrum / [<a href="http://www.micro.magnet.fsu.edu/optics/lightandcolor/sources.html">http://www.micro.magnet.fsu.edu/optics/lightandcolor/sources.html</a>]. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | <p>Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Black-Body Radiation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: - A continuous spectrum emitted by a black body at a certain temperature / Steel / &gt; 1570 K / 820 K / Stars. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation.</p>                                                                                                                                                                                                                                                                                                                                                                                                      |
| Technical commentary        | <p>This slide is about Black-Body Radiation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: - A continuous spectrum emitted by a black body at a certain temperature / Steel / &gt; 1570 K / 820 K / Stars. The slide groups them because one object or quantity is processed into another result used later in rendering.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Why it matters              | Even a sparse slide usually names a relation you must be able to explain in words.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you turn 'Black-Body Radiation' into a causal sentence instead of repeating the slide title?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Black-Body Radiation' introduces a graphics object, operation, or relation that belongs to the rendering workflow. The named terms describe what data enters the step, what operation changes or classifies that data, and what result is passed onward. The terms form an input-operation-output relation: Stars / <a href="https://www.tec-science.com/thermodynamics/temperature/black-body-radiation/">https://www.tec-science.com/thermodynamics/temperature/black-body-radiation/</a> 23/06/2026 10. The slide groups them because one object or quantity is processed into another result used later in rendering. The object-level relation is input, operation, output, and later use. This is the basic shape of most computer graphics concepts: data is represented in one form, processed by a rule or algorithm, and then consumed by the next stage of image generation. |
| Technical commentary        | This slide is about Black-Body Radiation. The slide names a concrete relation between input data, an operation, and an output that another graphics stage can consume. The terms form an input-operation-output relation: Stars / <a href="https://www.tec-science.com/thermodynamics/temperature/black-body-radiation/">https://www.tec-science.com/thermodynamics/temperature/black-body-radiation/</a> 23/06/2026 10. The slide groups them because one object or quantity is processed into another result used later in rendering.                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | <p>The slide 'Spectral Density Function (SDF)' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Light spectra are represented as spectral density functions / - Spectral density functions provide the light intensity (=energy) per wavelength / 400 Wavelength <math>\lambda</math> (nm) 700 / ygrenE / 400 Wavelength <math>\lambda</math> (nm) 700. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type.</p> |
| Technical commentary        | <p>This slide is about Spectral Density Function (SDF). The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Light spectra are represented as spectral density functions / - Spectral density functions provide the light intensity (=energy) per wavelength / 400 Wavelength <math>\lambda</math> (nm) 700 / ygrenE / 400 Wavelength <math>\lambda</math> (nm) 700. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | <p>Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | <p>The slide 'Light Perception' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Humans perceive light spectra / as differently colored lights / - Often described using three / main properties (HSL/HSV model) / - Hue - primary color tone. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type.</p>                                                                                                          |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Technical commentary | This slide is about Light Perception. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Humans perceive light spectra / as differently colored lights / - Often described using three / main properties (HSL/HSV model) / - Hue - primary color tone. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. |
| Why it matters       | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself       | Can you identify the normal, light vector, view vector, and material term relevant to 'Light Perception'?                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Professor-style explanation | The slide 'Interpreting SDFs' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Shape of an SDF depicts how humans perceive represented light / - Hue: dominant wavelength / - Saturation: % of energy in dom. wavelength / - Luminance: total energy (SDF integral) / 400 Wavelength $\lambda$ (nm) 700. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Interpreting SDFs. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Shape of an SDF depicts how humans perceive represented light / - Hue: dominant wavelength / - Saturation: % of energy in dom. wavelength / - Luminance: total energy (SDF integral) / 400 Wavelength $\lambda$ (nm) 700. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Interpreting SDFs'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Professor-style explanation | The slide 'Representing SDFs' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - In spectral rendering SDFs are discretized as arrays / - Cell number represents differentiable wavelength ranges / - Cell values represent energy per wavelength range / - Much more frequently SDFs are represented as three-channel color / - HSL values are derived from SDF. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |

The terms describe an occlusion test: - In spectral rendering SDFs are discretized as arrays / - Cell number represents differentiable wavelength ranges / - Cell values represent energy per wavelength range / - Much more frequently SDFs are represented as three-channel color / - HSL values are derived from SDF. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Check yourself              | Can you decide whether 'Representing SDFs' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Source cue                  | How to represent light sources in computer graphics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Professor-style explanation | The slide '8.2 Light Sources' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: How to represent light sources in computer graphics. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Technical commentary | This slide is about 8.2 Light Sources. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: How to represent light sources in computer graphics. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. |
| Why it matters       | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                      |
| Check yourself       | Can you identify the normal, light vector, view vector, and material term relevant to '8.2 Light Sources'?                                                                                                                                                                                                                                                                                                                  |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Professor-style explanation | The slide 'Light Sources' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - All light sources have a RGB color property representing their SDF / - Light sources are also defined through their location, orientation and extent / within a virtual scene / - Different light source types omit different spatial properties / - Light sources have no associated geometry. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Light Sources. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - All light sources have a RGB color property representing their SDF / - Light sources are also defined through their location, orientation and extent / within a virtual scene / - Different light source types omit different spatial properties / - Light sources have no associated geometry. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Professor-style explanation | The slide 'Point Light Sources' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Point light sources $L = P, C$ have a geometric center $P = (x, y, z)$ / and radiate light with color $C = (R, G, B)$ evenly in all directions. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Point Light Sources. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Point light sources $L = P, C$ have a geometric center $P = (x, y, z)$ / and radiate light with color $C = (R, G, B)$ evenly in all directions. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Point Light Sources'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Cone Light Sources' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Special point light source with geometric center / - Radiation of light restricted to a cone-shaped area with its tip in the center / - Specified by cut-off angle and exponents for the decrease / of brightness with distance to the center / (spot light exponent). Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Technical commentary | This slide is about Cone Light Sources. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Special point light source with geometric center / - Radiation of light restricted to a cone-shaped area with its tip in the center / - Specified by cut-off angle and exponents for the decrease / of brightness with distance to the center / (spot light exponent). Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. |
| Why it matters       | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Check yourself       | Can you identify the normal, light vector, view vector, and material term relevant to 'Cone Light Sources'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Page 19                     | Light Attenuation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Source cue                  | - Light attenuation is inversely proportional to the square / of the distance $d$ between the light source and the object / - Attenuation factor / $f = \min, 1 / att c + c \cdot d + c \cdot d^2$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Professor-style explanation | The slide 'Light Attenuation' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Light attenuation is inversely proportional to the square / of the distance $d$ between the light source and the object / - Attenuation factor / $f = \min, 1 / att c + c \cdot d + c \cdot d^2$ . Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Light Attenuation. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Light attenuation is inversely proportional to the square / of the distance $d$ between the light source and the object / - Attenuation factor / $f = \min, 1 / att c + c \cdot d + c \cdot d^2$ . Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Light Attenuation'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Area Light Sources' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Light source with geometric center and geometric extension / - Mostly of planar shape / - Transmission of light over the entire surface analogous to a point light source. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Area Light Sources. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Light source with geometric center and geometric extension / - Mostly of planar shape / - Transmission of light over the entire surface analogous to a point light source. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Area Light Sources'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Professor-style explanation | The slide 'Directed Light' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Infinity-far away imaginary light source / - Light rays run parallel and evenly throughout the scene, / direction is specified as a vector / - Light intensity does not diminish / with increasing distance. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing.    |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Technical commentary | This slide is about Directed Light. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Infinity-far away imaginary light source / - Light rays run parallel and evenly throughout the scene, / direction is specified as a vector / - Light intensity does not diminish / with increasing distance. Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. |
| Why it matters       | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself       | Can you decide whether 'Directed Light' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Professor-style explanation | The slide 'Local vs. Global Illumination' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Simple case: Local lighting / - Consideration of direct illumination by light sources / (without obstacles or reflection) / - Simplified light models approximate / real lighting effect. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Local vs. Global Illumination. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Simple case: Local lighting / - Consideration of direct illumination by light sources / (without obstacles or reflection) / - Simplified light models approximate / real lighting effect. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Local vs. Global Illumination'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Professor-style explanation | The slide 'Ambient Light' explains the problem of deciding which surface is actually visible from the current viewpoint. Many primitives can project to the same image region, but only the nearest relevant surface should determine the opaque color at a pixel. Different algorithms solve this relation in different spaces: object-space methods sort or split geometry, image-space methods subdivide regions, ray methods query visibility along viewing rays, and the depth buffer compares per-fragment depth values. The terms describe an occlusion test: - Undirected light rays, evenly distributed / - Light intensity constant, regardless of distance / - Simulates general room brightness (basic brightness). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint. The object-level relation is viewpoint, candidate surface, visibility rule, and visible result. This relation is the reason that fragment generation and final pixel color are not the same thing. |
| Technical commentary        | This slide is about Ambient Light. The visibility method on the slide decides which surface, fragment, ray hit, or image region is visible from the current viewpoint. The terms describe an occlusion test: - Undirected light rays, evenly distributed / - Light intensity constant, regardless of distance / - Simulates general room brightness (basic brightness). Candidate surfaces or ray hits are compared so the renderer can decide which object is actually visible from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Why it matters              | Visibility decides which generated candidates are actually seen from the current viewpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check yourself              | Can you decide whether 'Ambient Light' works per object, per image region, per ray, or per fragment?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Source cue                  | How to represent materials in computer graphics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Professor-style explanation | The slide '8.3 Material Models' explains how scene objects exist before they are rendered. A 3D model is not an image yet; it is a structured description of geometry and attributes. The central objects are vertices, edges, faces, triangles or other primitives, and sometimes additional data such as normals, texture coordinates, colors, materials, or connectivity. The terms describe model representation before rendering: How to represent materials in computer graphics. Geometric primitives define shape, vertices provide positions and attributes, and later pipeline stages transform, project, rasterize, and shade that representation. This matters because the rendering pipeline needs this representation as input. The model describes what exists in the scene, while later stages decide where it appears, which parts are visible, how it is sampled into fragments, and how it is shaded into final pixel colors. |
| Technical commentary        | This slide is about 8.3 Material Models. The slide describes scene objects before rendering: geometric models, primitives, vertices, topology, attributes, and the representation used as input to the pipeline. The terms describe model representation before rendering: How to represent materials in computer graphics. Geometric primitives define shape, vertices provide positions and attributes, and later pipeline stages transform, project, rasterize, and shade that representation.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Professor-style explanation | The slide 'Material Models' explains how scene objects exist before they are rendered. A 3D model is not an image yet; it is a structured description of geometry and attributes. The central objects are vertices, edges, faces, triangles or other primitives, and sometimes additional data such as normals, texture coordinates, colors, materials, or connectivity. The terms describe model representation before rendering: - Material models capture the different properties of materials / - Materials can have a wide variety of appearances / - Different groups of materials can be classified / based on appearance / - Metal - shiny and specular appearance. Geometric primitives define shape, vertices provide positions and attributes, and later pipeline stages transform, project, rasterize, and shade that representation. This matters because the rendering pipeline needs this representation as input. The model describes what exists in the scene, while later stages decide where it appears, which parts are visible, how it is sampled into fragments, and how it is shaded into final pixel colors. |
| Technical commentary        | This slide is about Material Models. The slide describes scene objects before rendering: geometric models, primitives, vertices, topology, attributes, and the representation used as input to the pipeline. The terms describe model representation before rendering: - Material models capture the different properties of materials / - Materials can have a wide variety of appearances / - Different groups of materials can be classified / based on appearance / - Metal - shiny and specular appearance. Geometric primitives define shape, vertices provide positions and attributes, and later pipeline stages transform, project, rasterize, and shade that representation.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Why it matters              | Model slides explain the input objects that later transformations, projection, rasterization, and shading operate on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Check yourself              | Can you name the geometric objects and attributes represented by 'Material Models' before rendering begins?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Page 26                     | Materials vs. Textures                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Source cue                  | - Material models specify the material properties for an infinitesimal surface / - No material variance with respect to location is supported / (i.e., structures such as wood grain cannot be represented) / - Textures are able to support material variance with respect to location                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | <p>The slide 'Materials vs. Textures' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs:</p> <ul style="list-style-type: none"> <li>- Material models specify the material properties for an infinitesimal surface</li> <li>- No material variance with respect to location is supported (i.e., structures such as wood grain cannot be represented)</li> <li>- Textures are able to support material variance with respect to location.</li> </ul> <p>Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type.</p> |
| Technical commentary        | <p>This slide is about Materials vs. Textures. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs:</p> <ul style="list-style-type: none"> <li>- Material models specify the material properties for an infinitesimal surface</li> <li>- No material variance with respect to location is supported (i.e., structures such as wood grain cannot be represented)</li> <li>- Textures are able to support material variance with respect to location.</li> </ul> <p>Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Materials vs. Textures'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Professor-style explanation | The slide 'Light Material Interaction 1/3' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Material appearance is influenced by three wavelength-dependent effects / - Reflection - light energy bounces off / - Absorption - light energy is reduced / - Transmission - light passes through the object (refraction occurs) / $R$ = reflected energy. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type. |
| Technical commentary        | This slide is about Light Material Interaction 1/3. The lighting objects on the slide combine normals, light directions, view directions, material coefficients, and shading locations to compute color. The terms describe local shading inputs: - Material appearance is influenced by three wavelength-dependent effects / - Reflection - light energy bounces off / - Absorption - light energy is reduced / - Transmission - light passes through the object (refraction occurs) / $R$ = reflected energy. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Why it matters              | Lighting formulas are only meaningful when their vectors and material terms are interpreted correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Check yourself              | Can you identify the normal, light vector, view vector, and material term relevant to 'Light Material Interaction 1/3'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Professor-style explanation | <p>The slide 'Light Material Interaction 2/3' explains how a visible surface point receives color from local lighting. The surface normal gives the orientation of the surface. The light vector gives the direction from which illumination arrives. The view vector connects the surface point to the observer, and the material parameters decide how strongly the surface reacts with ambient, diffuse, or specular reflection. The terms describe local shading inputs: - Material properties determine weight of the individual effects / opaque colored material opaque black material / <math>A &gt; 0</math> , <math>T = 0</math> , <math>R &gt; 0</math> <math>A = I</math> , <math>T = 0</math> , <math>R = 0</math> / perfect mirror material transparent material / <math>A = 0</math> , <math>T = 0</math> , <math>R = I</math> <math>A \sim 0</math> , <math>R \sim 0</math> , <math>T \sim I</math>. Surface position, normal, light direction, view direction, and material response combine to produce the final color contribution. The object-level relation is light source, surface point, normal, material response, and computed color. The visual behavior changes when any of these objects changes: a rotated normal changes diffuse brightness, a different view vector moves the specular highlight, and different material coefficients change the perceived surface type.</p> |
